BARR'S SEED GUIDE NOW READY (FREE).

BARR'S SEEDS

OF FINEST SELECTED STRAINS AND TESTED GROWTH

THE BEST SEEDS IN THE WORLD for securing a supply of Vegetables "the year round," and for keeping the Flower Garden always gay, and with abundance of Flowers to cut for vases and bouquets; also Seeds of Plants for Greenhouse decoration summer and winter.

BARR'S SEED GUIDE contains a select List of the best Vegetables and the most beautiful Flowers for Garden and Greenhouse. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. SENT FREE ON APPLICATION.

BARR'S 21/- COLLECTION OF VEGETABLE SEEDS contains a liberal assortment of the following useful Vegetables: Beans (Broad and French Beans), Beet, Borécole, Broccoli, Brussels Sprouts, Cabbage, Capsicum, Carrot, Cauliflower, Celery, Colewort, Corn Salad, Cucumber, Cress, Endive, Herbs, Leek, Lettuce, Melon, Mustard, Onions, Parsley, Parsnips, Peas, Radish, Salsify, Savoy Cabbage, Scorzoneria, Spinach, Tomato, Turnip, and Vegetable Marrow.

OTHER COLLECTIONS of BARR'S VEGETABLE SEEDS, 5/6, 7/6, 12/6, 42/-, 63/-, and 105/-.

These Collections sent carriage paid on receipt of remittance. Full particulars on application.

BARR'S CHOICE FLOWER SEEDS.—The "Seed Guide" contains a Select List of all the most beautiful Annuals and Perennials. Special Collections for all purposes, and many Sterling Novelties.

All Seeds sent Carriage Paid on receipt of remittance.

BARR & SONS,

For 1900,

OF

Vegetable & Flower Seeds

AND

BULBS & PLANTS

IS NOW READY.

Will be sent Post Free on application to their Offices at OVERVEEN, near HAARLEM, HOLLAND, or to their GENERAL AGENTS—

Messrs. MERTENS & CO.,

3, CROSS LANE, LONDON, E.C.

No. 1019.—VOL. XL., THIRD SERIES.

ECKFORD'S SPECIALITIES

ONLY GENUINE DIRECT FROM WEM
AWARDED 46 GOLD & SILVER MEDALS

SWEET PEAS!

The BIGGEST SUCCESS of all is ECKFORD'S GIANT SWEET PEAS. The PURITY and STAMINA of these Home Grown Stocks are so conserved by SPECIAL METHODS of CULTURE that the seeds are PHENOMENAL for UNRIVALLED STRENGTH and VITALITY, and with proper cultivation, give the HIGHEST POSSIBLE MAXIMA of results! Prizes offered in 1900 alone exceed £40!

Collections from 1/6 upwards.

(See particulars in Catalogue.)

See beautiful plate of SWEET PEA NOVELTIES for 1900, sent gratis with each Catalogue.

CULINARY PEAS!

ECKFORD'S CULINARY PEAS are positively UNRIVALLED by any on the Market for FLAVOUR and CROPPING CAPACITY! ENORMOUS YIELDS under favourable conditions. Collections for 5 months continuous supply (See page 2 Catalogue.)

PURE VEGETABLE SEEDS!

Results from ALL QUARTERS prove that ECKFORD'S SEED, for PURITY, VIGOUR, and YIELD, are the CHEAPEST and BEST ever offered to the Public! Collection for 12 months supply, 12/6, 21/-, 42/-, 63/-, 105/-, all carriage paid. Other Collections, 2/9, 5/-, 7/6, post free.

CINERARIA (SILVER MEDAL STRAIN). Giant Flowers, splendid habit, unequalled!
PRIMULA SINENSIS. Unique Novelties and Grand Collection of named varieties
PANSY. World-famed strain of FANCY, SHOW, PEACOCK, and FLAKED VARIETIES!
VERBENA. RENOWNED RACE of EXCEPTIONAL MERIT!

Don't buy till you have seen it! **ILLUSTRATED Catalogue & Cultural Notes POST FREE!** If you love Gardening send for one!

HENRY ECKFORD,
SEED GROWER, WEM, SHROPSHIRE.

Journal of Horticulture.

THURSDAY, JANUARY 4, 1900.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 12, Mitre Court Chambers, Fleet Street, London.

NEW YEAR'S ADDRESS.

A MIDST the gloom which has settled over our country, recalling as it does the terrible days of the Crimean War and the Indian Mutiny, it is difficult perhaps to write on any subject which does not bear directly or indirectly on the war; but it behoves all good citizens to remember that they have duties of various kinds, which must be carried out, notwithstanding the adverse circumstances in which we are placed, and consequently I feel that the pleasant duty which I have for many years discharged of sending a word of greeting to the readers of the Journal must not be omitted.

Of course, as far as I am personally concerned, it must be a matter of deep satisfaction to me that my health and strength enable me to do this. To one who is far advanced in his eighty-second year it is not likely that the opening year of the twentieth century should be so full of glowing anticipation as it will be to so many; but withal, I do not desire to write in too melancholy a strain, and, indeed, as far as horticulture is concerned, this is not necessary.

On every side we see signs of progress; the number of persons interested in their gardens increase year by year, and although most quarters of the earth have been ransacked for that which affords one of its chief charms—the introduction of novelties—every now and then there crops up something that brings an additional pleasure to the cultivator. Then, for those "who sit at home at ease," there is garden literature enough to satisfy the most hungry searcher after new ideas. The course of events has run smoothly on. There are no fiery contests and fierce controversies which I can remember in years past, and those who wish that their last years should be spent peacefully will welcome all this, and be glad that they have no longer to brandish their blackthorn or shake their fist in the face of an opponent.

We naturally look to the condition and progress of the Royal Horticultural Society as the great central exponent of horticulture in the kingdom. Under its present able management it is always endeavouring to search out for some new departure,

E. B. HAWTHORN & CO., Ltd., London Works, READING. (Name Paper.)

and the past year has witnessed another of its successful efforts. The holding of a Conference on Hybridisation to which foreign growers should be invited was a happy idea which met with general assent, and those who know the hospitality with which English horticulturists are received abroad, were glad that the intention to invite some well known hybridisers from the Continent and from America was carried out. Not only was the Congress held and valuable papers read and heard, but the foreign visitors were invited to share the hospitality both of the Royal Horticultural Society and of the Horticultural Club. These reunions were very pleasant, and were highly appreciated by those who were invited to share them. This was, of course an extraordinary work of the Society, but its routine operations were carried out with the same care and energy as before.

The Temple Show was, as usual, a magnificent spectacle, which no other country in the world could produce. We are sometimes asked why a more artistic display is not made at this show, and we are invited to copy some of the foreign exhibitions with their waterfalls, rivulets, and other pretty adjuncts. Well, simply this is not our way of doing things, and we prefer the plan of giving the plants the greatest liberty to show forth their charms. One thing, however, may be said, that it is a great pity there is no change from year to year of the formal arrangements that are made. One could with tolerable certainty determine in which part of the tents each collection would be found.

The early date on which the Temple Show is held, and the character of the exhibits, which are all produced under glass, render them independent of the weather, and therefore that important element of horticulture does not come into play, unless it be in the retarding or hurrying on of certain products. But the grower of plants out of doors has again had a very hard time to put up with; it was very nearly a repetition of 1898, we had the same periods of cold winds and long and very trying drought. These things have their effect on fruit and vegetables, especially Pears and Apples, from which, owing to the extent of their blossoming we were prepared to look for a good crop, but on the whole it was a very partial one, or, as we say in this county, "a very spotty one"—that is, in some places and on some trees a plenty, and in others none, while everything was turned topsy-turvy in the flower garden. Roses were very late, and many herbaceous plants which delight in moisture succumbed altogether. It is to be hoped our droughty seasons are drawing to a close. We have had a good cycle of them, and yet after all I think one would prefer them to such terrible seasons as 1879, when day after day rain fell and the corn rotted in the fields.

The year has not been remarkable for the introduction of any great novelty in flowers, and it must be in some out of the way corner whence such novelties should come, for all parts have been invaded by the zealous explorer, and yet now and then something does turn up. For instance that very beautiful Lily, *Lilium rubellum*, which has been imported in large quantities by Messrs. Wallace and Co. and others. At the Drill Hall meetings of the R.H.S. all novelties worth recording have been exhibited and decorated, and it is somewhat curious to see in what regular lines these novelties run. Among Orchids awards of merit have been given to twenty-five Cattleyas, sixteen *Lælio-Cattleyas*, and thirty-seven *Odontoglossums*. I wonder if any Orchid grower cultivates all these, which year by year are produced. We florists used to be jeered at for growing collections of flowers which we said were distinct, but in which the general public could see very little if any difference. What a multitude of *Cypripediums* have been raised within the last few years, and yet the raising of new ones goes on.

Beside Orchids more homely flowers have been raised and exhibited in large numbers, and awards of merit have been given to twenty Carnations, twenty-eight Chrysanthemums, twenty-nine Dahlias, most of these being of the Cactus type, which is considered now more suitable for decoration, while the old Show Dahlia has very much declined in public estimation. In two favourite flowers, the Narcissus and the Rose, not many new varieties have been produced; the rage

for the former flower has somewhat declined, and no wonder, for the production of varieties has been pushed to a ridiculous extent. The Rose holds its own, and will always do so I think, but of the large number raised on the continent (about sixty or seventy every year), very few find their way to our gardens.

I should be glad to know if there is any other pursuit which provides its lovers with such a wealth of literature as does horticulture. Week after week the serial productions demand the attention of its votaries, but whose appetite is so voracious as to be able to devour them all. In books we have had that delightful volume by Miss Jekyll, "Wood and Gardening," which ought to elevate the tastes of those who consult its pages; then there is also a very pleasant book, not strictly horticultural, but written by one who has taken a prominent position, and who has been for some years a member of the Council of the R.H.S., Mr. Henry J. Pearson, who graphically describes his journey in Nova Zembla, called "Beyond Petsora," although his researches are mostly ornithological; and here I may perhaps say without vanity that I have just passed through the press a new edition of a little book I published some years ago, "Roses for Amateurs," and I do not think it is often given to one in his eighty-second year to carry out a work of this kind.

Special societies have, I think, had a good time of it. The National Auricula has increased its numbers; the Carnation and Picotee Society, under the fostering care of Mr. Martin R. Smith, is in a flourishing condition; the Chrysanthemum Society also seems to be prospering, as also does the Dahlia Society, although it has to mourn the loss of its accomplished President; while the National Rose Society closes the year with a larger balance than it has ever had. I can say very little about the Royal Botanic Society, for I am ignorant of its proceedings, but I believe it goes on its usual way. The Crystal Palace under its new management seems likely to find favour, and unquestionably there is no place in or near London where horticultural shows can be held with such pleasure to all concerned.

And now we come to what is always the sorrowful part of my little address, the calling of the death roll, and few years are full of sadder memories than that which is now closing around us. First and foremost was the patriarch of horticulture—Mr. John Lee—who entered into rest ere yet the first month of the year was gone. How little one thought that when that accomplished French horticulturist, Mons. Henry de Vilmorin, was over with us at the Conference in July, he was to pass away so soon for ever from us. He was fond of our country and people; he was an accomplished gentleman who spoke our language with fluency, his diction was always happy and refined, his manners were genial and his conversation piquant. Many of our leading members, such as the late Dr. Hogg and Mr. Harry J. Veitch, were his intimate friends, and he has left a blank which it will be impossible to fill.

Then there was my dear old friend Frank Rivers, who carried on at Sawbridgeworth the work begun years ago by his esteemed father. Between them they enriched our gardens and orchards with many valuable productions in flowers and fruits; Mr. Rivers' father was at one time a most successful grower of Roses, but his son did not take so much to them as to fruit, to which he was devoted; how genial and pleasant he was, and what a fund of anecdote and general information he had. I used to enjoy very much my chats with him at the Horticultural Club, and one of my first questions to him used to be, "Well, Rivers, what new books?" and I was always sure to get a list of some worth reading; his last illness was protracted and painful, causing great regret to his friends.

Dr. S. P. Budd of Bath was also a great loss to horticulture; of course from the distance we were from one another I saw little of him, but he was for many years a successful competitor at the exhibitions of the National Rose Society, and was twice the holder of its challenge trophies.

Another of this Society's most distinguished members passed away in the person of Mr. T. W. Girdlestone. He was well known to many of the readers of the Journal, and had done much, both by his writings and energy, to forward the culture of the flowers in which

he was specially interested—namely, the Rose and the Dahlia. He was a constant and successful exhibitor of the former for many years, but latterly his exertions had been confined to the Dahlia, more especially to the single varieties. He had initiated a race of dwarf plants, and the manner in which he used to exhibit these evidenced great taste. He was a sharp critic and keen observer; for many years he had compiled the list of new Roses which the N.R.S. printed as a guide to exhibitors, and there was no person whose opinion on the merits or demerits of a Rose was more reliable.

The closing days of the year brought with it another great loss, the Right Hon. Lord Penzance, who passed away in December at the advanced age of eighty-four. His name will continue to be associated with the new race of hybrid Sweet Briars as the Penzance Hybrids. In the "Rosarian's Year-Book" for 1892 he gave an interesting account of his proceedings in this matter, and fairly set forth his successes and his failures. He brought out some fifteen or sixteen varieties, but I do not think that any of them excelled or even equalled the first two which he originated, Lord and Lady Penzance.

And now, my dear friends, having thus lightly touched upon the matter connected with the past year, let me give a word of encouragement to you for the future. I am rather like some of those old soldiers who have suffered in our wars, and yet with what deep thankfulness I can look on the pleasure which my garden has afforded me. It is true I can now only hobble about and partially enjoy the sight of the flowers I have loved so well, but this is what I must expect: the sportsman has to lay aside his gun, the angler can no longer throw his line, the huntsman's pinks are only contemplated as a thing of the past. All these may indeed tell what they have done in years gone by, but they are only memories, and he is wise who can be contented to regard them as such. When someone said to Talleyrand that he did not play whist, "But what will you do my dear fellow," he said, "when you come to be old?" and yet the time came when the old diplomatist could not distinguish a club from a spade.

And does not all this teach us that we ought to be looking forward to a better and more enduring inheritance? The teaching of Scripture with its figurative language makes a garden of trees and flowers as the future home of the saints. Strive then so to fulfil your duties that when you are enjoying the products of your gardens you may be encouraged to cherish those blessed hopes that our Heavenly Father has given you to cheer and strengthen you in your pilgrimage, and that you may be, as I say once again, a partaker of that Tree of Life which is in the midst of the Paradise of God.—D., Deal.

CAMELLIA BUDS DROPPING.

I AM glad to see a writer ("W.") recording the cause of failure by Camellias dropping their buds. It is refreshing to read records of this nature, as we are accustomed so much to read of successes. Deficient root action always causes bud dropping; much fire heat is another cause which is often overlooked; strong heat in the pipes is adverse to Camellia management at any time, and the forcing of the plants should be done during the growing season between April and July.

While I am thoroughly in touch with "W." I am prompted to refer to a case of "dropping," which troubled me somewhat. Buds which were set thickly on plants of the old double white dropped in great numbers. I found that the soil had been allowed to shrink from the sides of the tubs, which was only partly filled by careless hands when surfacing the soil was done after the plants had flowered and were starting into growth. The water ran down the sides of the balls, which effected growth formation, but plenty of buds were set which fell off in hundreds just before they should have opened.

When I discovered what was wrong, I filled up the space between

the roots and tubs, which was not more than half an inch wide. A smooth stick with sharp point was probed as deeply into the ball of soil as possible, and as thickly over the surface as could be done. The holes were filled up with dry sandy soil, and a good coating of soil and plant manure was placed over the surface.

The plants recuperated after the whole ball was well moistened, and are now laden with opening buds, and foliage green and glossy.—M. TEMPLE, Carron, N.B.

PALMETTE VERRIER PEAR TREES.

It was after an interval of many years that I called at Oldlands, near Uckfield, in Sussex, on the 27th of last March, to see some of the trees which I planted there about twenty-seven years ago. On the west side of the east kitchen garden wall there are nine palmette verrier pear trees, whose appearance was so striking that I asked Mr. Fitt, the very able and courteous head gardener, if he would kindly have them photographed for me. He did so, and I now send you a reduced plate of half of them (fig. 1), hoping that if it can be published in the Journal it may induce more general attention to the beauty and utility of trees of this form.

FIG. 1.—PALMETTE VERRIER PEAR TREES.

They are on the free stock, are perfectly healthy, affording a splendid object lesson in training so as to secure an equable distribution of vigour. In horizontal trees of such an age the lower branches would be enfeebled and worthless, but this can never happen to palmette verriers, because the tips of the branches are on a common level. It is simply owing to this that the lower branches, from their greater length, become under development the most useful, and they remain so always. This is so obvious that one really wonders at the general clinging to horizontal training.

It may be interesting to add that the tree in the foreground is that king of autumn Pears, Fondante d'Automne. In the last edition of the "Fruit Manual" Dr. Hogg appends to his description of it my note: "The fruit is large and handsome, of most delicious flavour, and is one of our best October Pears." That was a fair description of fruit gathered from this tree. It is also noteworthy the tree next it on the left, which is not shown in this plate, is a grand tree of Beurré Clairgeau. This Pear is usually only second rate, but on this western aspect, and in the favourable climate of Sussex, it was really excellent. Three years after the planting it had some fine fruit, most attractive in its rich colouring of red and yellow, of which my note says "it was gathered on October 12th, was in use throughout November, being very sweet, rich and juicy, with a delicious aroma." The other trees shown in the illustration are Josephine de Malines, one of the best late Pears, Beurré Rance, Maréchal de Cour, and Williams' Bon Chrétien.—EDWARD LUCKHURST.

FLOWERING TREES AND SHRUBS.

WHILE so much is being done towards the adornment of the flower garden it is surprising how few of the many beautiful flowering trees and shrubs are requisitioned, even in some of the best kept gardens; they are equally hardy, and no more expensive than many of the commoner kinds which we find so often repeated. Rhododendrons, Laurustinus, and Laburnums are still deserving of cultivation, but others may be planted that will vastly increase the beauty and enhance the charms of the garden.

We will begin with the Rhododendrons. Fine hybrids can now be procured in almost endless variety of colours and shades, and what can excel the massive beauty of their flowers? Can anyone but admit that they are simply magnificent? There is no difficulty in selecting varieties with foliage as hardy and as beautiful as a Laurel. But while admiring the hybrid Rhododendrons, we are even more charmed by their near allies, the hybrid Azaleas, which are quite hardy in many parts of the kingdom, but are seldom seen except treated as pot plants. A bed of Azaleas has no parallel amongst flowers with its dazzling shades of colour, ranging from the soft tints of primrose, sulphur, and yellow to the more radiant glories of apricot, salmon, orange, and vermilion. The perfume, too, is most delicious—an aroma which clings tenaciously, evaporating not, but permeating all around.

Passing on again, we have the great wealth of hardy Heaths, and their near allies the White Irish Heath (*Menziesia polifolia alba*), with its profusion of waxy blossoms, equal in appearance to the chaste bells of the Lily of the Valley. The plants continue to bloom for three or four months during spring and summer. *Kalmias*, also members of the Heath tribe, do not flower freely in some parts of the kingdom, but where they can obtain sufficient moisture to prevent the foliage becoming browned by the sun, then they ought to be planted extensively. Both *K. latifolia* and *K. myrtifolia* may safely be planted in moist sandy loam, near the sides of lakes or similar situations, and where they often receive partial shade. The wax-like flowers and foliage are really beautiful. Then, again, we have the beautiful spring flowering *Andromedas*, with their creamy white bell-like blooms, which are far from being sufficiently appreciated, for where compact plants of dwarf growth are required these do duty in a twofold form, with their charming flowers and fine foliage.

But what of the *Berberis*? Do we see these represented as often as they deserve? Of all small flowering shrubs what is finer than *B. Fortunei*, with its different shades of leaves, varying from green to yellow, and salmon to vivid red; or *B. Darwini* and *B. stenophylla* when laden with their rich gold and bronze-coloured flowers, the latter possibly the prettiest of all. And these are plants specially adapted for small gardens, as they may be pruned and kept to any size required. We cannot pass by the dwarf, compact-growing *Daphne cneorum*, with its rosy umbels, giving such a sweet fragrance that one is loth to leave it, even to have a peep at its near relative *D. mezereum*. The former will not thrive everywhere, but might well be extensively tried. It likes an open sunny spot during the summer, with a free root run in good sound loam. *D. mezereum* is a British plant which early in spring, sometimes as early as February, is covered with showy pinkish-red blossoms, and is one of the most valuable of spring flowering shrubs which ought to find a place in every garden. The hybrid white variety is also equally attractive.

Of the Snowballs the old *Guedres Rose* is the most popular, but that beautiful free flowering variety *Viburnum plicatum* is the finest, surpassing all others in habit, foliage, and flowers. The disposition of this plant to bloom profusely whilst quite small is not the least of its merits, to cause it to be justly considered one of the most valuable ornamental shrubs in cultivation. Much might also be written in favour of the hardy *Spiræas*, with their graceful spikes, plumes, and panicles, but many are not met with so often as they deserve. Of these *S. Fortunei* is worth attention as a plant which thrives in almost any soil and aspect, with grand deep rose coloured flowers; whilst the larger leaved *S. Lindleyana*, with its large terminal panicles of white flowers forms a remarkably handsome shrub in autumn when few others are in flower. The charming *Hydrangea paniculata grandiflora*, with its immense panicles, literally covering the branches with the flowers of changeable shades from pure white to pink, ought to be in every garden.

Of flowering shrubs in the latter part of summer we have few of any recognised merit. But what are more telling than some of the varieties of *Hibiscus*, yet how meagrely are they represented in most gardens. A group comprising both the double and single varieties in their different colours is fine, and almost as bright and cheerful looking in August and September as anything we have in spring.

Besides the foregoing there are many trees and shrubs, alas! too little used, which deserve a place in any garden; some on account of their peculiar and telling foliage, others their coloured fruit or berries, or strange habits of growth. No garden can be at all complete, or even satisfactory, without its complement of trees and shrubs. But

while enumerating only a few, there are many others which we hope to see more extensively cultivated, and to which we may at some future time refer.—T. GEE.

SILICO-FLUORIDES.

IT will, perhaps save trouble to such of the readers of the *Journal of Horticulture* as are interested in the various matters connected with the use of silico-fluorides in the garden, if you will allow me to point out that the silico-fluoride of ammonium affords a ready means of preparing any other silico-fluoride that may be required. For example, if the silico-fluoride of potassium is wanted, all one has to do is dissolve in rain water or distilled water some salt of potassium, such as the sulphate, chloride, or nitrate (saltpetre). On adding the silico-fluoride of ammonium to such solutions the silico-fluoride of potassium is immediately precipitated, while the sulphate, chloride, or nitrate of ammonium, as the case may be, remains in solution. Probably most people would use the nitrate of potassium for this purpose; saltpetre is tolerably cheap, and the nitrate of ammonium which results is a very powerful and valuable fertiliser.

The same remarks apply to the soluble salts of sodium and calcium; all are precipitated by the silico-fluoride of ammonium. Sodio silico-fluoride is slightly soluble in water (five pints dissolve 0.625 oz.), but the other silico-fluorides mentioned above are practically insoluble in cold water, so that they can be easily washed free from traces of other substances. For the guidance of your readers, the following data as to solubilities will be useful:—

Potassic sulphate dissolves in 11 times its weight of water.

„	chloride	„	4	„	„	„
„	nitrate	„	4	„	„	„

The sulphate, chloride, and nitrate of ammonium are much more soluble than the corresponding potassium salts, so that the silico-fluoride of ammonium may be used dry, and stirred directly into the various solutions. The quantity of it which must be used is as follows:—

1 oz.	potassic sulphate	requires	1.02 oz.
1 „	„ chloride	„	1.19 „
1 „	„ nitrate	„	1.76 „

Advantage may be taken of the foregoing facts by anyone who is troubled with hard water and prefers soft. Stir into a tub of hard water silico-fluoride of ammonium until a piece of blue litmus paper is turned red when dipped in. Then add a little more water, and continue to do so until the red litmus paper, when dipped in, regains its blue colour. As soon as the water has had time to settle, the tub will contain pure water with a little carbonate of ammonia in it, while the lime and other impurities will be in a solid state at the bottom. Carbonate of ammonia soon evaporates from any leaves upon which it may be sprayed, and meanwhile does them no harm.—W. MILLS.

— THE CULTIVATION OF MUSCAT GRAPES.—A report from the "Isle of Wight Express," of a voluminous paper by Mr. W. Tribbick, Brook Gardens, has been sent to us, and from which we take a short extract:—"I have grown Muscats for twenty years, during which period many gardeners competent to judge have affirmed that as a house of those Grapes mine would compare favourably with any in this country. They were also once considered so meritorious as to secure me a substantial rise of wages, not the least acceptable I can assure you of honours won. My vinery is 50 feet long, with inside border 12 feet wide, composed of rather calcareous fibrous loam, cut from down, where sheep are constantly grazing. This was taken 3 inches in thickness only, six months before required for use, first stacked for the decay of grass, afterwards broken not too fine. To each waggonload of this was added ten barrowloads of old plaster and lime rubble, five of wood ashes, five of gritty washings from high road water tables, and half a cwt. of very small bone. This compost was turned many times, the whole of the ingredients being thus well incorporated with each other. Very strong canes were planted in May, and permitted to grow quite naturally, without stopping or pinching, covering all of the roof before growth was completed. They were pruned back to 3 feet from the bottom of the rafters, and the following year allowed to carry three or four branches each. Some cultivators consider it unwise to commence cropping permanent Vines thus early, but I contend this had the desired effect of checking the almost too luxuriant growth made, and aided the production of full crops in shortest possible time. An initial mistake often made is in cutting back one or two buds, young Vines that have grown with exceptional freedom. This results in such excessive vigour as to make them unproductive the following season. Our Vines at the next pruning were shortened back to 9 feet, and carried nine or ten bunches to each rod of well-finished fruit, and the next year a full crop of fourteen bunches equally good. I prune on the spur system, but I have three times in twenty years run up new rods, four of the Vines having now two rods each, or fourteen in all, on which I annually secure about 200 bunches."

THE LATE DUKE OF WESTMINSTER, K.G. AN APPRECIATION.

To the general public his Grace was perhaps best known as a philanthropist of the highest order, and as a patron of the turf in the noblest and purest sense of the term. He was nevertheless greatly interested in horticulture, and gave freely of his large means for the encouragement of the educational and exhibitiv side of the art; a liberal supporter of the R.H.S., as well as a regular contributor to the funds of the various gardening charities, these institutions shared in his generous munificence. On the Eaton estate the Cottagers' Horticultural Show, which was started some years ago at the suggestion of his Grace, was a model of its kind, and in this both the late Duke and the Duchess took more than an ordinary interest.

The Chester Paxton Society from its inception benefited largely by his patronage and practical support, and on several occasions he delivered addresses at the opening ceremonies of its annual fruit and Chrysanthemum exhibitions, and his utterances on those occasions showed how keenly he was alive to the importance of extended fruit culture in our country. To the writer his Grace more than once deplored the apathy which this important industry received at the hands of those to whom it might easily become a source of income.

Of a highly cultured and refined nature, no one was a better judge of all that was beautiful in floriculture, and he made no concealment of his distaste for any productions in the shape of monstrosities. As an evidence of this, at one of the exhibitions just mentioned he described a group of perfectly grown Japanese and incurved Chrysanthemums to the writer as a collection of "mop heads," at the same time putting in a plea for more extended culture of the single varieties. Flowers which combined simplicity with delicacy and beauty appealed to him in a far greater degree than anything in the way of the large Chrysanthemum.

In the magnificent and well-appointed gardens of Eaton the Duke took a special pride, and appreciated greatly the efforts of his respected chief in this department, Mr. N. F. Barnes. No one lived more for others than did the noble Duke, and nothing gave him greater pleasure than to see his fellow men participating in and sharing the luxuries with which he was surrounded. It was always his desire that from the highest to the lowest the gardens at Eaton should at all times be accessible, a nominal charge being made only to excursionists during the summer months, and the sum thus realised was included with others for the benefit of the local hospital, the finances of the institution in this way being each year augmented by a total sum of not less than £500.

In addition to this, religion, philanthropy, science, literature and art, in fact everything that tended for the benefit of the people, received of his goodness. The Grosvenor Museum, Chester, which is now one of the best appointed institutions of its kind in the provinces, will ever stand out as a lasting monument to his memory, and it was here that one of his last public appearances in the old city was made, the occasion being the presentation of prizes of the Kingsley Memorial Fund of the Chester Society of Natural Science, Literature and Art. His loss to the country is great, and the citizens of Chester in particular mourn for one who was the city's greatest benefactor in every respect.—GEORGE PAXTON.

BROCCOLI NOTES.

A VERY dry period set in about the time our Broccoli and other greens were planted, many of the plants being destroyed both by the Turnip beetle and the drought. For some time they made little growth. Towards the end of August and the early part of September, however, the plants appeared to take a new lease of life, and grew rapidly, although the long looked for rain had not come. We experienced some heavy dews at this time, and these were, no doubt, the cause of the improvement taking place.

Although making such a bad start I must admit that my crop of Broccoli had never looked better, and as far as the early kinds are concerned, produced finer heads. It is rather too early to say much about the winter and later varieties, as we have already had a taste of severe weather, and perhaps may have more, although the frost has not been so severe in our garden as it has been in many places. The lowest registered has been 14°, 15°, and 16°, and I do not think any injury has been done.

A breadth of Veitch's Self-protecting Autumn Broccoli, one of the best for giving an autumn and early winter supply, has produced some grand heads, they being firm, compact, and white, many of them growing to a large size. This is a well known variety, and a good one to follow Autumn Giant Cauliflower. If a few rows are planted a little later than the general planting, heads may be cut well into the new year during a mild winter. We have cut useful produce as late

as the middle of January. Snow's Winter White is a good old standard variety, being one of the whitest and best Broccoli with which I am acquainted. It is a useful one to follow the last named. In some catalogues this variety is stated to be hardy, but this does not correspond with my experience. During severe winters I have found a much larger percentage killed than has been the case with several other varieties. Indeed for a few seasons I did not grow it for this reason. This year, however, it finds a place, about 150 plants being grown, which will soon be ready for use if the weather remain open.

Backhouse's Winter White and Knight's Self-protecting are a little later than Snow's, and are good hardy sorts to grow, but do not give such "refined" heads. Leamington is another fine old variety, and for general purposes one of the best. For giving a later supply we have two very good varieties in Sutton's Late Queen and Veitch's Model. The former is rather dwarf, having curly, dark green leaves, its habit making it fairly hardy. In this garden it never produces very large heads. Model lasts a little longer than Late Queen. It is a stronger grower, and produces heads of a conical shape. When walking round the gardens at Castle Howard last spring Mr. A. E. Sutton drew my attention to a large plot of this variety, and spoke very highly of it. He also asked me to examine two very fine heads he had marked, and if I remember rightly he intimated that they would be saved for seed.

When a border on the north side of a wall can be spared for a few plants of those late sorts, heads may be cut to a much later period. In the open garden during late spring the days are often very hot and bright, and the heads come in too quickly.—J. S. U.

PRUNING EVERGREEN SHRUBS.

THIS, I venture to think, is a matter that cannot be too often brought into notice, inasmuch as the proper pruning of evergreen shrubs, even by otherwise intelligent cultivators, is more honoured in the breach than in the observance. The apparent neglect by many owners of shrubs in the timely pruning or regulating of especially choice specimens is owing to a fear of or reluctance in manipulating them according to their needs, and the operation is postponed until eventually drastic methods are obliged to be adopted. This often results in the disfigurement of the tree, whereas an annual or other periodical application of the pruning knife would have obviated such severe measures as indicated. To none more than, for instance, Rhododendrons and the common Laurel do these remarks apply. Both, however, are readily amenable to the pruning knife or the saw and the "hedge-hook;" but where the work must be neatly done in regard to the cutting-back of old-established bushes with large limbs the latter tool may be dispensed with.

For hiding unsightly objects quickly a hedge or wide belting of the common Laurel is frequently employed; but if neglected in the matter of pruning the plants soon become naked beneath and top-heavy, thus defeating the object in view, and the only remedy is to adopt the drastic and undesirable operation of cutting them down nearly to the ground or replacing, if immediate effect is desired, by new bushes. I am cognisant of several instances at the present time which could be adduced in support of the argument indicated.

Regarding the period of the year for operating on neglected old Laurels, or, in fact, almost any other evergreen shrub, undoubtedly springtime is the best, when the sap is rising and the naked cutback branches and stumps are not unsightly so long as when the operation is performed in the autumn or winter time. There is also danger of severe frost killing them outright when cut back so early. The pruning may be done even later, but without so satisfactory results, as the force of the sap has become expended and the buds do not break so well. It is usual with cultivators to leave the pruning of Rhododendrons till after the flowering period, but when the bloom is scanty and the bushes require severe cutting, the operation is best performed in early spring, so as to afford a longer period for the ripening of the young shoots before the following winter. The only advantage that can be advocated in favour of the autumn or winter pruning of shrubs and trees is where labour is limited, and there is such a multiplicity of operations cropping up in spring that were the pruning deferred till then the chances would be that the work would have to be left until the autumn or winter following.

Connected with the manifold duties of the gardener there are few more interesting and requiring more judicious care than pruning ornamental shrubs and trees, so varied are they in their individual characteristics. In conclusion, I may add that it is excellent practice, time allowing, of course, to make it a rule, when passing any shrub requiring the removal of an obtrusive or half-worn out straggling branch, to cut it away instantly, and not defer the operation until a more favourable and indefinite opportunity.—W. G.

CRIMSON CARNOT.

AMONGST Japanese Chrysanthemums there is no type more popular than that known as the "Carnots." Of this family we have the original Madame Carnot, still I think the best of white flowered varieties, the rich yellow G. J. Warren, and the primrose Mrs. Mease, a charming trio truly. Next season we are promised the pink form; one of our leading specialists is in possession of several plants of this pleasing addition to the family. We now learn of a further addition, and a glorious one it will be—a crimson form of this elegant type of Japanese variety. From the appearance of the specimen in front of me I predict, if all goes well, it will cause a furore amongst Chrysanthemum worshippers, especially when it is known that the purchase of the stock will run into three figures.

ROBERT LAIRD.

This is an Australian seedling sent for distribution to Mr. Wells by Mr. John Pockett. Like many others of the strain this new Japanese bids fair to rank amongst the best of white flowered varieties. The florets are below medium width, each one curls at the tip, adding much to the beauty of the flower, which is of full size, quite solid, and with a stout peduncle.

YELLOW PRINCESS VICTORIA.

The parent of this sport is well known as one of the best late white flowering varieties, the semi-recurving flat florets rendering it a most useful decorative variety. The footstalk is stout, which is an all-important point in Chrysanthemums for vase decoration in a cut state. The yellow sport is an exact representation of its parent, and should prove most useful.—E. MOLYNEUX.

LETRIER.

"W. S., Wilts," asks (page 561) for the names of better late varieties than those he enumerated. I send a few flowers of Letrier which I consider excellent. As "W. S." says, Niveus and Lady Lawrence are very liable to fungus. If you can find any on either of the enclosed examples of Letrier, please say so. I have not one plant more than 4 feet high, including the pot. This is a French variety, and I shall be much disappointed if it does not become one of the best known Chrysanthemums. A pure white Etoile de Lyon is what I should describe the flower.—W. WELLS.

[The flowers were excellent, and if everyone who grows Letrier can produce specimens of equal merit at the new year the variety is sure to become popular.]

CHRYSANTHEMUM RUST.

IN Mr. Godfrey's Chrysanthemum list, just to hand, I find that he treats somewhat largely of that pest, the rust on Chrysanthemums, and propounds various recipes for checking its development. But it is interesting to find in dealing with this evil the remark put into italics, "I can positively state that affected plants have been sent out by every Chrysanthemum specialist in the kingdom." That is a strong assertion, and of necessity includes himself. Mr. Godfrey, I observe, strongly advises the use of that excellent instrument the "Abol" syringe, as with its curved nozzle it can be so readily used to spray the under sides of the plants and leaves. That is one fact of which all Chrysanthemum growers should take note, as the syringe is not costly, and may be found useful for the spraying of many plants besides Chrysanthemums. Mr. Godfrey specially advises for spraying the use of the well-known Bordeaux mixture on plants growing in the open ground in August and September, which is, of course, a big job, but seems to be by results amply repaid. Then he also strongly advises the use of sulphide of potassium, half an ounce to a gallon of water; but the sulphate of copper and lime solution seems to be best. These are remedies, or may it be said preventive applications, that applied in time seem to be efficacious, and may be obtained and used by everyone. We infer from the concluding paragraph of the rust remedies that no one need be alarmed concerning the pest if they will but take means to check its progress in good time, and not after it is too late.—A. D.

AGRICULTURE IN THE WEST INDIES.—We learn that his Excellency Sir John Hay, K.C.M.G., Governor of Barbadoes, has promised to meet the representatives of the various West Indian agricultural societies at Bridgetown on January 6th, 1900, and welcome them to an Agricultural Conference. Dr. D. Morris, C.M.G., is President of the Conference, and will open the business by addressing the gathering. By this means it is hoped that the scope of agricultural operations in the West Indies will be enlarged, and land industries more widely recognised and encouraged.

RHODODENDRON DAURICUM.

ALTHOUGH this cannot be classed as a first-rate garden plant, yet, flowering as it does in the winter, it forms a welcome addition to the very few outdoor flowering plants of this season of the year. A native of Dahuria and Mandschuria, it commences to grow and flower early in the season, a fault common to several plants from this region, and which, except in sheltered spots, deprives us of many useful and beautiful garden plants.

The flowers of *R. dauricum*, or *R. dahuricum* as it is often called, open between December and February, are about an inch across, of a bright purplish-magenta colour, and rather thin in texture, and, although spoiled by sharp frosts, will stand 5° or 6° without injury while the unopened buds do not suffer, but will expand later when the weather is more favourable. The leaves are small, being a little over an inch long by half an inch in width, and many of them are shed in the autumn, though it is not entirely deciduous. When bruised, the leaves and stems have an aromatic odour somewhat resembling that of Eucalyptus.

The chief point in dealing with this Rhododendron is to give it a warm sheltered spot, with a good background of evergreens, which will serve to show its brightly coloured flowers to the best advantage. When fully grown it forms a plant about 3 or 4 feet high with a rather upright habit.—C.

PEARS DECAYING AT THE CORE.

"SLEEPY" Pears we have long known, and I certainly have known some friends who professed to prefer them. Personally I never objected to their preference; in a large family, if one prefers the sleepy ones, there is all the more of the perfect condition left for the majority. But Mr. G. Abbey has told us that this "sleepy" condition is after all only the Pear in a far more lively form, many of them in this state swarming with bacteria. I have known several persons who liked Pears in this condition, but I do not recollect that any of them, after their enjoyment of this bacterial repast, were the worse for the meal, and yet it seems gradually forcing itself upon us that these atoms, if I am not calling them by a name that is far too large for them, are at the root of a very large share of the mischief which comes upon the human race.

Providentially there would seem to be in us beneficent germs that feed on the noxious varieties, and though the cry is, Still they come, and new forms seem to be continually cropping up, we may hope that these beneficent friends will be equal to the occasion. Alas! I am much afraid that the Pear is deficient in these beneficent germs to devour the destructive bacteria, if we may judge from this exhaustive report of Mr. Abbey (page 389, last vol.). I am a devoted lover of the Pear, believing it when in its best condition one of the grandest of our English fruits; but I gather from this report that the different varieties will require different soil, and that in our small gardens will be well nigh impossible. I note another point—namely, that on "stronger land," or after a "strong soil was given," then instead of ripening, the fruits rotted at the core. Were similar bacteria in this stronger soil? Can they get from one to the other?

My Doyenné du Comice trees failed this year to give me a single fruit, and it is additional news that *Monilia fructigena*, which I fancied loved the Plum and the stone fruits, will also attack the Pear. I found early this season several small Pears infected by the Pear midge (*Diplosis pyrivora*). I was thinning a tremendous crop of Marie Louise d'Uccle. The fact of finding this scourge for the first time in my garden, though I heard of it four or five miles off last year, made me give up thinning, fearing I might cut off good fruit, and I left the infected ones to disclose their injured condition later. The consequence, of course, has been that the large crop of fruit is nothing like so fine as usual. The large early-thinned fruit, I mean those picked off as nearly ripe, matured beautifully, and were excellent eating; but the smaller and late-picked fruit is now developing rapidly, increasing soft spots, whilst one cut through a day or two since, a large fruit, was a marbled brown completely through, without showing this much externally.

I expect the remainder now on my shelves will only reappear as stewed Pears, by no means bad in that way, but still not to be compared with the perfect ripe fruit. Now, as I must do something to check this pest on my Plums, which has robbed me of every fruit on my Jefferson the last two years, I propose to give the Pear trees as well a double syringing of sulphate of copper (1 lb. to 25 gallons of water) whilst resting, and again when the buds begin to swell; I have a sort of hope that the Pear midge may find this disagreeable, as I have no desire to see him or his offspring again.

Of late years we seem to be realising that the curse of sin is heavy on us; it is not only that "in the sweat of thy face thou shalt eat bread," but our fruits are also to be obtained under similar conditions, if at all. No one who has not seen the effect of the brown rot fungus on the Plum could imagine that a wealth of bloom

and abundant setting should still be utterly unequal to the task of bringing one single fruit to anything approaching its fair proportions, either in size, beauty, or use; nothing, in fact, but shapeless, rotten deformity.

Surely the labours of our friend Mr. Abbey, Miss Ormerod, and others, are not a bad answer to the question in another page of the same number of our Journal that "Gardening is advancing."

Evidently, if bacteria are a new development of this century, they are come to stay; they meet us now at every step, and it is against them that so many of our battles will have to be fought. I have tried Mr. Fenn's anti-blight on several things this year, and think it decidedly checks some of these troubles, but I think I have used it too late, forgetting, alas! that "Prevention is better than cure."

And now, Mr. Editor, I must stop, yet as somewhat bearing on this important subject I would crave space for this amusing sketch, which appeared some ten or fifteen years ago in the columns of "St. James's Gazette," and which is certainly worth reproduction. It was entitled:—

THE LOVES OF THE BACILLI.—A PHYSIOLOGICAL IDYLL.

(The Comma Bacillus is, according to Koch, the germ of cholera.)

Quoth Bacillus to Bacilla
(Surely everything has sex);
It is quite enough to fill a
Soul with pride, to see the necks
Of these mighty men of science
O'er the microscope bent low,
While beneath them in defiance
Spins the merry Vibrio.

Proud am I to think, my Comma,
While the world rolls on its way,
Every fell disease springs from a
Fairy filament, they say.
Autocrats, that tower Titanic
Have been known to bow to me;
Mighty potentates in panic
Disinfect at thought of thee!

Rash would he be, who should presage
That no germs behind us are;
We are part of that great message
That outrings 'twixt earth and star.
What by thousands or by tens is
Multiplied, in vain they show;
Something lies beyond his lenses
Mortal man may never know!

We are greater, my Bacilla
Than all monarchs; for meseems
We need but exist to fill a
Strong man's brain with fever-dreams.
Such the thought, my passion kindles
O my microscopic bride:
Kiss me! although twenty Tyndalls
Have their eyes upon the slide!—H. S. C.

There is plenty of space for deeper thoughts in several of these lines.—Y. B. A. Z.

PRUMNOPITYS ELEGANS.

THIS is one of the few Chilean Taxads that can be grown outdoors in this country, being of about the same degree of hardiness as *Araucaria imbricata*, though it is far less fastidious with respect to soil. On the Andes of Chili, where it occurs frequently, it forms a small tree 40 or 50 feet in height, well furnished with spreading or sometimes drooping branches; but in this country it forms a dense, pyramidal tree about 15 feet high, well clothed with rather stiff branches to the ground.

When young the plants are nearly always of an upright habit, but with age they gradually broaden at the base, and assume a pyramidal form. It can be propagated from seeds or cuttings, but the young plants should be in a sheltered situation for a year or two, as severe weather kills the growing points, and causes the plants to become stunted, a state which it is very difficult to get them to grow out of.

The leaves are linear in shape, about an inch long, of a deep green above and glaucous beneath, and are densely clustered around the branches. The name of the Plum Fir is sometimes applied to this plant, probably on account of its purplish fruits, which are about the size of a Grape, and are said to have an agreeable flavour when ripe. There are probably no trees in this country large enough yet to bear fruit, so the question of edibility must be left to the future to decide, but judging from nearly allied plants which have fruited, the fruits will probably smell much better than they taste.

This plant is sometimes known under the name of *Podocarpus andina*, but *Podocarpus*, though a closely allied genus, has its fruits solitary on a fleshy stalk, while in *Prumnopitys* they are borne on a loose spike. In other respects the two genera closely resemble each other.—C.

VIOLETS FOR EXHIBITION.

"A. J. L." (page 521) says, "So far as I know these popular flowers are not represented at our shows for competition." In this he is not quite correct, for at some West of England shows prizes are offered for them staged in glasses with their own foliage; it is true, however, they are not encouraged as they might be. This is, I believe, only a matter requiring time, for Violet cultivation is being taken up more freely than has ever previously been the case.

The exhibits of Messrs. House & Son, Westbury-on-Trym, have done much to popularise Violets, both for home use and exhibition. They have a large area of land set apart for the newer varieties, and it would seem their cultivation has arrived at a high stage of perfection, judging from the size of the flowers and the length of the stalk. Violets are favourites with everyone, and it is a matter of some surprise that prizes should not have been offered for them before.

The great numbers of Chrysanthemum shows that are crowded into the space of a month render it impossible for a tithe of the varied exhibits to be noticed in reports, and it is not unlikely that this has led your correspondent into thinking they are not favoured with a place in prize schedules. These newer Violets are well adapted for growing in pots, and at some shows prizes are offered for them up to a limited size, and it cannot be disputed but that such a class would be popular.

Violets in frames for winter buttonholes have been found in most gardens for many years, in some cases, too, in which a frame or two furnish the whole extent of glass. Since the introduction of Californica, Princess of Wales, and others of kindred type, even in small gardens one finds Violet culture taken up with much greater enthusiasm than in former days, and if this continue—as is certain—they will in time become standard exhibition flowers and plants. Chrysanthemum societies can do a great deal to extend this newer phase of Violet culture by offering liberal prizes for these fragrant flowers at their autumn shows.—W. S.

XL ALL VAPORISING COMPOUND AND THE PHARMACEUTICAL SOCIETY.

It is strange that the XL All compound should not have been attacked before now. How is it that they have left it alone until it has become known to practically every horticulturist in the kingdom, and has become almost indispensable for use in the garden as an insect destroyer? It has been suggested that had not the trade in this gardener's requisite developed to its present proportions, the attention of the Council of the P.S. would not have been drawn to it by its members. Why this sudden discovery of the fact that the XL All compound is a preparation which contains a percentage of nicotine? And why are they so fearful that someone will drink it, when it is manufactured and sold expressly for fumigating greenhouses? Why has it taken six years for them to discover that this is so dangerous, after it has been sold by nurserymen, seedsmen, and florists for this length of time without a single accident? To all unbiassed minds the answer suggests itself.

It appears that neither the Pharmaceutical Society nor its members have any control over the sale of carbolic acid or its preparations, and these can be freely purchased anywhere for domestic use, and seem to stand about some households quite unguarded. If this and other poisons of a similar character can be and are sold without any restrictions for household purposes, surely the horticultural trade may claim the right to sell a preparation of nicotine for use (quite apart from the dwelling house) in greenhouses, which in nine cases out of ten would be stored in an outhouse in the garden.

It is the opinion of many that all interested traders who have suffered from similar interference at the hands of the P.S. should organise a society to watch over their interests, and to bring their grievances before Parliament at the earliest date possible, with a view to getting the Act of 1868 amended, so as to enable agents other than pharmacists to sell poisonous preparations for technical purposes (in the manufacturer's original packages) to the trades and professions, which in the ordinary course of business it should be their legitimate right to supply, of course under necessary restrictions.

The Pharmacy Act of 1868, as affecting the sale of poisonous preparations for technical purposes, does not appear to be understood by one and all alike. It must be clear to all but the most nervous people that the skill of a pharmacist is not at all necessary to sell a farmer a tin of "sheep dip." Why, then, should he not be able to get it from the same source of supply as his other farm requirements?

Again, why should a gardener not be able to order his fumigator or weed-killer from his nurseryman or seedsman together with his bulbs or seeds, thus saving the expense and annoyance of having to obtain one requisite from one source and one from another? Next we shall hear of nurserymen and seedsmen being prosecuted selling any kind of insecticide, and bulbs and seeds containing poison may not go exempt.

I shall be glad to receive communications and suggestions from anyone who is willing to join such a movement as is above indicated.—G. H. RICHARDS, 128, Southwark Street, London, S.E.

RECENT WEATHER IN LONDON.—The closing days of 1899 were particularly pleasant, the sun shining brilliantly for several hours. The early hours of the new year, however, brought a change in the form of a heavy fog, which was followed on the evening of Monday, Tuesday, and Wednesday with heavy rain.

— WEATHER IN THE NORTH.—The last fortnight of the year was marked by variable weather. Up to the 23rd ult. dull days with sleety showers were occasionally brightened by gleams of sunshine. Frost then set in, which increased in intensity till the 28th, when 23° were recorded. Thaw followed on the afternoon of that day, and the year closed with three days of cold highish winds and drizzly showers. New Year's Day was dull and cold, 4° of frost being registered in the morning.—B. D., *S. Perthshire*

— ROYAL HORTICULTURAL SOCIETY.—The first meeting of the Committees of the Royal Horticultural Society in 1900 will be held as usual in the Drill Hall, James' Street, Westminster, on Tuesday, January 9th, 1 to 4 P.M. The Scientific Committee will meet in the library on the same day at 4 P.M.

— THE EPPING FOREST COMMITTEE.—On the motion of Mr. Edward North Buxton, J.P., it has been resolved that the members of the Committee express their great indebtedness to Mr. John Lobb for the admirable manner in which he has fulfilled the requirements of his office. He has exhibited, the resolution states, an earnest desire for the welfare of the Forest, and the interests of the public therein, and has devoted much valuable time and unremitting attention to the work of the Committee. By the able, urbane, and impartial manner in which he has presided over their deliberations, he has greatly aided his colleagues, and fully earned their hearty acknowledgments.

— THE CHISWICK POTATO TRIAL.—I am pleased to learn that it is Mr. S. T. Wright's intention so far as is practicable to act upon a suggestion I recently made, that in conducting the trial of early Potatoes determined upon at Chiswick this year, planting of the same varieties early and late in rows side by side will be made, so that apart from the merits of the individual variety, the best time for planting may be tested also. All those who purpose sending in varieties for trial, and only quite early ones should be so sent, should not only send as soon as possible, but also sufficient tubers to enable this duplicate planting to be carried out. The trial would in such case be all the more interesting. There are very many first early varieties in commerce, the merits of not a few of which are little known. It will be specially interesting to note how far from out of the legion of new varieties the old Ashleaf Kidney maintains its reputation for earliness. The trial should, if growth be not checked by frost, prove to be one of exceptional interest.—D.

PERISTROPHE SPECIOSA.—About three-quarters of a century has passed since this plant was introduced to English gardens, and like many other good old things it has been pushed into the background by more recent introductions. That it is worth growing is apparent from its effective appearance in the few places where it is well grown. It is an Indian plant, and under good cultivation makes a bush from 3 to 4 feet high, which from Christmas onwards for eight or ten weeks makes a very fine show with its pretty purple flowers. To have it at its best, cuttings should be rooted each year, old plants being thrown away. Cuttings may be inserted in sandy soil in March; they root readily, and require growing on quickly without a check until autumn. A mixture of two parts loam to one of leaf mould and one of decayed manure is a suitable compost, and 7 or 8-inch pots will be found large enough for the largest plants. Frequent pinchings will be found necessary until the end of July. When the pots are well filled with roots, feeding must be attended to. A cool, airy house is the best place for the plants after they have become established in their final pots, and growth should be completed by the end of October. Insect pests must be well looked after, as one of the most important things is to keep the leaves healthy.—W. D.

— GARDENING APPOINTMENT.—Mr. Jas. Gibbins, for six years general foreman at Knowsley Hall, has been appointed head gardener to the Earl of Sefton, Croxteth Park.

— LIVERPOOL HORTICULTURAL ASSOCIATION.—On the whole, the Liverpool Horticultural Association has had a very fair year, and the annual dinner, which is to take place at the celebrated Bear's Paw Restaurant on Saturday, January 20th, is certain to bring together a large company. No better musical programme could be arranged than that got up by the sub-committee. The speeches, once so full of interest, have disappeared during the past year or two, and if the speakers lacked eloquence I could have understood it, but in this respect Liverpool can hold its own, and a few toasts are always appropriate at least once a year. Not only as a member of the Committee, but as a representative of many others, I would ask those responsible to revive once again a much enjoyed custom.—R. P. R.

— JUDGING MELONS.—How unconsciously has Mr. Temple in his note on this subject last week emphasised the need for tasting Melons in judging them when he said that the task was disagreeable, so many badly flavoured fruits to be tasted often producing nausea. Well, I have tasted a good many, and, like so many others, have not swallowed the flesh of an offensive Melon, as such ordeal was needless. But what an admission of the generally objectionable character of Melons shown for prizes is thus made, and what a strong argument is thus furnished in opposition to granting such things prizes from appearance only. I think that judges who do adopt the tasting test, as a rule, look for something besides mere sweetness. They look for soft, pleasant flesh, and good flavour. If these things are not found in Melons the faults lie not with the judges, but with the bad culture shown in producing them.—K.

— THE BANISHED EELWORMS.—When the Editor wrote his short note headed "Fungoid Diseases" on page 565, he did not, I fearfully expose what was in his mind. Doubtless courtesy towards friends kept him in restraint, for when he wrote with regard to "W. B.'s" intimation that he had with a mixture of Veltha and phenyle exterminated the eelworm, but did not know which ingredient did the business, "that probably Messrs. Wood and Co. would favour Veltha, and Mr. Abbey phenyle." Whilst the ordinary man might exclaim, "A plague on both your houses! it was neither ingredient, but it was the whitewashing and the fresh soil that got rid of the pests." Now had these wonderful chemical remedies been applied to the old eelworm infested soil, and "soaked" with them, and as a result had exterminated the worms, what a triumph would it have been for one remedy or both. But soaking fresh soil with them, that perhaps was entirely free from the pest, seems nothing to boast of.—A. D.

— READING GARDENERS' ASSOCIATION.—The annual general meeting of the Reading and District Gardeners' Mutual Improvement Association was held on Monday the 1st inst., and was well attended, the President, C. B. Stevens, Esq., occupying the chair. Before the usual business was commenced the President announced the Judges' awards in connection with the Essays arranged during 1899. They were as follows:—"The Planting of a Garden with Hardy Fruit Trees and Bushes." (Open to all). First, Mr. G. Hinton, The Gardens, Walmer, Reading. Second, Mr. E. Trollope, The Gardens, Coombe Lodge, Whitechurch. Third, Mr. C. P. Cretchley, The Gardens, The Honeys, Twyford. "Plants Suitable for Table or Room Decoration, and their Culture." (Open to assistant gardeners only). First, Mr. J. Botley, The Gardens, Blythewood, Maidenhead. Second, Mr. C. Townsend, Whiteknights Gardens, Reading. Third, Mr. T. Pembroke, Greenlands Gardens, Reading. The adjudicators were Mr. T. Turton, Sherborne Castle, and Mr. J. Hudson, Gunnersbury House. The annual report and balance-sheet were read by the Secretary, and proved of a very encouraging character. The election of officers for the ensuing year was then proceeded with. A feature of the meeting was a magnificent display of Primulas. Mr. Townsend, The Gardens, Sandhurst Lodge, showed *P. obconica rosea*; and Mr. F. Lever, The Gardens, Hillside, sent well grown *P. sinensis* in small pots, as well as good plants of *Lachenalia pendula*. Mr. Wilson, The Gardens, Redlands, exhibited well-coloured specimens of Newton Wonder Apples. The best thanks of the members present having been given to the exhibitors and to the past officers, the first meeting of 1900 was brought to a close.

— **DEATH OF MR. JAMES SELDEN.**—We learn with regret of the death on the 25th ult., at The Gardens, Brookwood Park, near Alresford, of Mr. J. Selden. He was erstwhile known as an exhibitor in the Kingston and Wimbledon district whilst gardener at Coombe Cottage, Kingston. Mr. Selden's decease was due to a severe attack of influenza, followed by pneumonia. The deceased was in his forty-ninth year.

— **RHODODENDRON INDICUM VAR. BALSAMINÆFLORUM.**—One is pleased to see that hardy flowering shrubs are having the prominence given to them that is their due in the columns of the Journal, and that the competent writers of the articles are doing them justice. "W. D.," in the article on "Hardy Peat-loving Shrubs," mentions *inter alia* that *Rhododendron indicum* var. *amœnum* is hardy as far north as Chester. I do not think that it is generally known that the exquisite little *R. indicum* var. *balsaminæflorum* is hardy here in the east of Kirkcudbrightshire and close to the Solway. It is a charming little shrub with double crimson flowers shaped like those of a *Camellia*-flowered *Balsam*, whence I suppose the name. I believe it is best known in gardens as *Azalea rosæflora*, but it has also been known as *A. Rollisoni* and *A. balsaminæflora*. It is grown on the top of a rockery but partly shaded by other plants. The soil is sandy peat. When Mr. James Backhouse of York was here in 1899 he was surprised to find it so hardy.—S. ARNOTT, *Carsethorn by Dumfries, N.B.*

— **BRISTOL GARDENERS' ASSOCIATION.**—The fortnightly meeting of the Society was held at St. John's Parish Room, Redland, on Thursday, 28th ult. A large number of members were present. The subject for the evening was "Mistakes in Gardening," introduced in a racy and exhaustive manner by Mr. Chas. Lock of Keynsham. Dealing with the subject generally, he suggested that many gardeners erred in judgment when they decided on the profession as a means of livelihood, and whilst the same might be said about any trade, he contended that no one who was not an enthusiast should adopt a vocation that claimed so much of the time and thought of the worker as did horticulture. He went very fully into mistakes amateurs and professionals made in various branches of their work, giving useful hints as to avoiding pitfalls, and concluded by pleading for more sympathy between gardeners and their employers. A short discussion followed, and Mr. Lock was heartily thanked for the paper. The President, H. Cary Batten, Esq., kindly offered three prizes for three plants in bloom in pots not more than 5 inches in diameter. For these there was good competition, the awards being:—First, 10s., Mr. McCulloch; second, 7s., Mr. Raikes; third, 5s., Mr. Ross. Mrs. Cary Batten kindly distributed the prizes, and in responding to a vote of thanks, expressed her regret at the absence of the President, her pleasure in being present at such an interesting gathering, and wished the Society every possible success.

— **EMIGRANTS' INFORMATION OFFICE.**—The January circulars of the Emigrants' Information Office and the annual editions of the penny handbooks show the present prospects of emigration. The notice boards are now exhibited, and the circulars may be obtained free of charge at nearly 500 public libraries and institutions throughout the country. It is too early in the season for the ordinary emigrant to go to Canada, unless he has friends to go to or money to keep him till the spring, when there is likely to be the usual demand for competent farm labourers. In New South Wales there is practically no demand for ordinary farm or station hands. In Victoria there is not much improvement in the general demand for labour, except that a considerable number of those out of employment have been set to work on railway construction. There has been a considerable amount of settlement on the land recently, and dairying has made special progress. In South Australia there has been a demand for farm hands, and for married couples without children for farm and station work. In Queensland there has been a general improvement in trade and in the demand for labour; the depression has almost entirely passed away, and the disposal of the unemployed has ceased to be a difficulty. There is a good demand for farm labourers. Free and assisted passages are now being granted to farm labourers. In Western Australia the population, though it has rapidly increased, is still small, and therefore the demand for all kinds of labour is necessarily limited. The chief demand is for farm labourers. In Tasmania the supply of farm labourers is sufficient. In New Zealand competent farm hands and shearers have no difficulty in getting work in country districts during the present busy season. With regard to South Africa persons are warned against going there at the present time in search of work.

— **DESTRUCTION OF ANTS.**—The latest method of destruction of ants is said to be the use of gasoline. Pour about a half pint of gasoline into the ant hill or nest, and set it afire. The gasoline will instantly spread through all the nest, and as the heat on the surface increases the gas will generate from the utmost recesses, and the fire will cook the ants. Half a pint of gasoline will burn from three to eight hours, and kill every ant in the largest nest, as well as all which attempt to enter it from without.—("Tropical Agriculturist.")

— **THE HORTICULTURAL DIRECTORY AND YEAR BOOK FOR 1900.**—The forty-first issue of this familiar annual, or handy book of reference in gardeners' homes and the offices of business men connected with horticultural pursuits, is now ready, and advertised in the present issue. It is larger than any of its predecessors, contains more addresses of gardeners than before, with changes received up to the time of going to press; also lists of nurserymen and florists at home and abroad; a descriptive register of new plants that were honoured during the past year; much information of permanent value, with a great variety of the best garden requisites of leading firms and representatives of the industry of horticulture. The work may be fairly described as a big shilling budget of gardeners and gardening.

— **ALOE SOMALIENSIS.**—This new species is flowering for the first time at Kew, the specimen being in the Mexican house. It was collected, together with *Kalanchoe flammea* and other things, by Miss Cole in Somaliland in 1895, and through her it reached the Kew collections. It is a dwarf-growing species, the plant in question being but a few inches high. It forms a dense rosette of leaves, which are from 5 to 7 inches long, $2\frac{1}{2}$ inches wide at the base, tapering to a point, the margins armed with stout prickles, and prettily mottled light and dark green in colour. The flowers are small and pink, produced in quantity on a branched raceme 2 feet in height. For lovers of succulent plants this will be a welcome addition, the marbled leaves being decidedly ornamental.—W. D.

— **THE WEATHER 100 YEARS AGO.**—According to a record in the "Annual Register" there were only 173 dry days in England in 1799. By a diary kept at Norwich the number is shown to have increased to 214 in 1800. There were twenty in January, twenty-three in February, fourteen in March, seven in April, twenty-three in May, sixteen in June, twenty-eight in July, sixteen in August, fourteen in September, seventeen in October, fifteen in November, and twenty-one in December.

— **SUSSEX WEATHER.**—The total rainfall for December at Abbot's Leigh, Haywards Heath, was 1.69 inch, being 1.05 inch below the average. The heaviest fall was 0.27 inch on the 29th. Rain fell on fourteen days. The total for the year was 31.14 inches, which is 1.43 inch above the average of twenty years. The average yearly fall for the ten years, 1880–1889 inclusive, was 30.65, that of the ten years, 1890–1899, was 28.77, thus reducing the average for the twenty years to 29.71 inches. The maximum temperature was 52° on the 1st, the minimum 16° on the 16th. Mean maximum 41.10°, mean minimum 30.17°; mean temperature 35.63°, which is 2.46° below the average of eleven years.—R. I.

A week of frost and rain with intervals of bright sunshine, and a gale on the 29th.

GREETINGS AND GRUMBLINGS.

"IN the dark and trying hour; in the breaking forth of power," comes another year. Brave sons of the empire—soldiers of the Queen! Is there any fellow feeling, apart from that of country, kith, and kin, engendered by what is essentially peaceful work? Peaceful work? "There is no peace for a gardener," said one of the craft lately. That is so; and where there is no peace then is there perpetual warfare to uphold the suzerainty of the gardener's empire, and that is so. "I'm killing 'em by millions," he continued, "and still they come." Sufficient here to "stagger humanity," or, at least, to startle that portion of it who, drawing so largely upon the gardening world for their necessities and luxuries, know not the great natural forces in continual and combined array against the man of peace (?)

They do not know, and it all looks so easy. "You just dig and sow, and plant, and hoe, to gather up the fruits and flowers in their due season." Would that some who think so lightly of gardening could gain a little insight; gather a little wisdom by reading the war correspondence gleaned from one year's pages only of the *Journal of Horticulture*. It would be to the mutual advantage of master (or mistress) and man if a little better understanding did exist on these matters; for what is not understood is always liable to be misunderstood, and, what is more, often is. Unfortunately gardeners as a rule seem to be the worst men in the world to give simple explanations of plain truths. "It's not a bit o' good argufying, just grin and bear it," was the precept of a past master; one who had unconsciously adapted to his wants and woes the old French motto, *Qui s'excuse, s'accuse*. Silence is not always golden.

If some men seek safety in silence, others in making rash statements find them recoil to their own detriment. "Well, sir, you see they breeds nine times every hour, and has nine at a time." Such was the actual conclusion, but not the final one, of an argument between another worthy man and his master anent that most insidious of bugs and beasties, the mealy bug. Facts and figures should clinch an argument. They did not, however, in this case, in spite of the remarkably precise birth rate statistics in point of time and numbers. It was regarded as a subterfuge to conceal sins of omission, and worse still, repeated by "the master" to his friends over the dinner table, by one of whom the writer was interrogated upon the matter, without much further enlightenment, may be added. A wider disseminated knowledge of these visible and invisible foes might, one thinks, often bring more sympathy and less blame to the man who is fighting them year in and year out. True, it will sometimes be heard in the gardening ranks, "My master," or "my mistress" (generally "my mistress"), "knows too much." But that's another grumble and another tale.

"A happy new year to you." No heartier exchange of the old familiar greeting is given than amongst the rank and file of gardeners. Such a grip has just been given to our hand by an old friend—so vigorous, so squeeze-ful, as to place that opinion beyond question, and accompanying the well worn wish so heartily, almost painfully, impressed was the hope that our "Mum" cuttings were making a good start. Ah! well, that's another tale, too. There is a good deal of human nature in gardening, and we know he wants to beat us at the show, and although that is still in the dim and distant future, he is looking ahead. He knows, as all real gardeners know, a good start means a good finish, provided, of course, the end is never lost sight of. Is there a gardener, may we ask, now looking over the new year's number of "our Journal" who, in turning over a new leaf, is not looking ahead?

1900. Cold, wet, peevish, piling last-born of Father Time! Who can discern in thy puckered lineaments what thou shalt do for us or against us? Why such perfervid greetings, dynamic hand-shakings, at the advent of one of whom little more can be said (and that is always safe to say of most infants), that it's like its father? "Like begets like." A few inches more or less in the rain-gauge; a few degrees up or down on the thermometer! The veriest trifles in the solemn march of time, in the sublime economy of Nature.

"How like eternity doth Nature seem
To life of man, that short and fitful dream."

Much they mean, we know, in garden work; but somehow those who have conquered in one direction are best braced to fight in another, to the end that unkindly elements are robbed of much of their severity. There is so much uncertainty about these new years, with corresponding anxiety, that one almost wonders why gardeners, of all men, should hail their birth with acclamation. "We live in hope," is a common saying. It might go farther by saying we live on hope, and true it is that without uncertainty there would be no hope, for it is the legitimate offspring of it, and, possibly, no living. What a tame thing gardening would be if returns were always reduced to the dead level of exact ratio to outlay! "Actions are ours, events are God's."

In endeavouring to forecast the horoscope of this new gift of time

any startling horticultural developments can scarcely be expected, although the craving for something fresh remains unabated. True, man's ingenuity and Nature's compatability are not yet exhausted, if ever they will be, and many novelties will, of course, appear with a flourish of trumpets, and eventually disappear in silence to swell that great crop in the land of the long-forgotten. A big trophy for Grapes, or something or other, is in contemplation to spur men on to deeds of derring-do. The 100-guinea challenge cup, shield, or vase, is a grand idea—at first sight; yet, somehow, the more one reflects upon it the more it seems to resolve itself into what an Irish friend calls a powerful weakness. Many, most of course, believe in it, but, like some precious relic upon which the eyes of the faithful may gaze but at rare intervals, it will of necessity be enshrined in some sanctuary, therefore, to most intents and purposes, be *non est*. There is just the wish, no more, that these honours and glories could be embodied in a more practical form. It is the wishing season, and having unselfishly lavished good wishes abroad among our fellow-men, we may, each and all, in the quiet moments of self-communion, come nearer home in these concluding apostrophic lines—

"Build thee more stat-ly mansions, oh my soul!
As the swift seasons roll.
Let each new temple, nobler than the last,
Shut thee from heaven by a dome more vast."

—A. N. OLDHEAD.

HARDY BORDER FLOWERS.

ANTHOLYZA PANICULATA.

ONE must speak of the Antholyzas among "hardy" flowers with some degree of reserve, as our experience of them planted in the border in this country is limited. One has, however, seen them grown under such diverse conditions that one feels justified in advising their more extended cultivation. Plants of such fine effect are none too plentiful, and their handsome leaves and distinct flowers will give a character to the border in which they are grown. They are bulbous plants from the Cape, but those which belong to tropical Africa are not adapted for the flower border and thus need no notice at present.

Perhaps the best for the garden of hardy flowers is *Antholyza paniculata*, which I think I have previously had the pleasure of naming in the *Journal of Horticulture*. It is a noble plant, with its fine, plaited leaves, and its tall many-flowered spikes with their bright red-yellow flowers. It will grow from 3 to 4 feet high. It comes from the Colony of Natal. *A. æthiopica*, which has some three varieties besides the type, is also a fine plant, but I do not think it is quite as hardy as the preceding. It also has red-yellow blooms. *A. caffra* has red flowers, and narrow, linear leaves. It was called by Sweet, *Anisanthus splendens*, and by Dean Herbert, *Gladiolus splendens*. *A. Cunoniana* only grows from 1 to 1½ foot high, and has red flowers. *A. quadrangularis* has variegated yellow and red perianths, the upper segment being red. *A. spicata*, *intermedia*, and *saccata* have never come under my observation in the open ground.

The Antholyzas ought, at least until we have further experience of their needs, to have a warm sheltered border in light soil, with a little protection in the way of cocoa-nut fibre refuse, dry leaves, or similar material in winter. I have seen them as far north as Stirlingshire growing vigorously, and without having had any winter covering. It has been recommended that they should be lifted annually to remove the offsets, but this is unnecessary, as they grow into fine clumps if left undisturbed for a longer time. The crowns of the corms ought to be at least 3 inches below the surface.

IRIS SUSIANA.

We are all apt to suppose that gardening is one of the exact sciences, and that if a plant does well with us under certain conditions it ought to do as well with others. But this is not the case. There are differences of soil or climate which may be inappreciable to us, but which to a marked degree affect success or failure in the cultivation of the plant or plants we want to grow. This is abundantly evidenced in the remarks on *Iris Susiana* (fig. 2) which have appeared in the *Journal* of late. That your able contributor "R. P. B." (page 540 last vol.) has succeeded in growing and flowering it most successfully without any artificial ripening is beyond question, but it is also undeniable that others who have grown it in a similar way have failed. It has been notorious for many years that it is not an easy plant to flower. That this was the case long ago is proved by the citation from Gilbert on page 540. His knowledge has been confirmed by generations of flower growers since his time.

Even yet we must, I think, confess that there is no "royal road" by which we can secure the annual flowering of either *I. Susiana* or the other *Oncocyclis* Irises. I dare not say that Rev. H. Ewbank's method is sure to result in success. This would be untrue, but it is correct to say that none have been so successful as he in flowering these wonderfully beautiful flowers. At the same time I would not venture to say that all those who followed Mr. Ewbank's plan were satisfied with the results. My experience in my own and other gardens is that it is not infallible, although the principle recommended is a

good one to follow in its main lines. Have we not Sir M. Foster's practice on almost similar lines? If I may be allowed to make a further remark, it is that we are as far off a diagnosis of the true cause of the failure of *Iris Susiana* as we were at first. We have, however,

IRIS KÄMPFERI.

I am anxious to return to this *Iris* very briefly with the object of bringing out more clearly the view I strenuously hold, that in most cases it is by no means necessary to keep the plants dry in winter.

FIG. 2.—IRIS SUSIANA.

apparently an agreement that Mr. Upex is not likely to succeed with his in their present place. Of the various *Oncocyclus* Irises that I have grown I find *I. lupina* the easiest to manage. It flowers in my garden under conditions in which *I. Susiana* is a complete failure.

This is not easily secured in many places, especially because at that time we have more moisture than in ordinary summers, when it has been recommended that they be kept moist. One may, for example, instance the plants in the bog at Glasnevin Royal Botanic Gardens.

There are often 6 inches of water over the soil in winter, yet it would be difficult to find healthier and more floriferous plants. This season I visited a Scottish garden where equally good results were secured, and the plants were on the margin of the lake, but in the water, all winter. I have plants doing equally well in and at the edge of water.

[If our several contributors can produce flowers equal to that portrayed by our artist it is only reasonable to suppose they will feel satisfied.]

ANTIRRHINUMS.

It is needless to say much about our old Snapdragons, which are known to everyone in the shape of *A. majus*, which is generally treated as an annual or biennial. One seeks, however, some information about one or two others mentioned in books, but, apparently, not available for gardens. These I do not know, but I am in hope that some readers may be able to give us information. One of these is *A. siculum*, with "white or yellowish, rarely purple, flowers," growing from 1 to 2 feet high. There is also *A. hispanicum*, with purple flowers with a yellow lip. It is said to grow 1 foot high. It has purple flowers, the corolla, according to the "Dictionary of Gardening," being the largest of the genus. Probably none of these are equal to our old *Antirrhinum majus*, which has in the course of years been greatly improved. *A. asarina* is better adapted for the rock garden than the border, and is, besides, not particularly hardy; although it proves hardier in some places than one would expect. It is not an erect but a procumbent plant, with greyish leaves and yellow and white flowers.

APHYLLANTHES MONSPELIENSIS.

This is a pretty and distinct little plant, which one very seldom meets with even in large collections of hardy flowers. It belongs to the Lily family, and has small heads of neat, deep blue flowers barely an inch across. The branches are like the leaves of the Rushes, and the leaves are absent; the flower scapes being leaf-like. The Montpellier *Aphyllanthes* is a native of France. It likes a light, warm soil and a sunny situation. It is increased by division. It cannot be called a showy plant, but is both interesting and pretty. It is fairly hardy under the conditions of cultivation suggested.—S. ARNOTT.

COMBATING CANKER.

It seems to be a general drawback of the leaflets emanating from the Board of Agriculture to leave altogether out of account the facts which practical experience has slowly accumulated, and to draw the line at scientific teaching. The one published in October was fairly well equipped in this respect, but the leaflet on canker quite eclipses that. The worst of such teaching is that those who are attached, perhaps a little unreasonably, to old-fashioned views, and who give little if any attention to what science has done, not only in the elucidation of the forces at work which cause disease, but also of the means for combating these forces, become disgusted, and fail to reap any benefit from papers otherwise suggestive.

The question of spraying in winter may in some instances prove not without value, though where trees are not permitted to grow beyond easily manageable dimensions its necessity is not so apparent, provided methods already in practice, such as excision of diseased wood, are carried out, such promoting a healthy root system in appropriate soil. The advice to discard varieties of fruit notoriously susceptible of infection is commendable, for though canker, like other diseases of a fungoid character, is somewhat mysterious, there is nevertheless no difficulty whatever in detecting certain Apples that canker, by its virulence, renders unprofitable to cultivate in some positions.

But the writer of the leaflet has made a mistake in too closely identifying certain kinds, as under every circumstance, or in every locality positively under the power of canker. What is the fact is that many Apples, of which I may name such well-known varieties as Cellini, Lord Suffield, Stirling Castle, Wellington, Blenheim Pippin, Cox's Orange, and Gravenstein, from a list that might be considerably extended, are in some gardens apparently canker-proof, and in others so susceptible of attack as to be practically not worth growing. These are matters which give a more or less unsatisfactory flavour to the whole, a particular kind of scientific teaching that ignores practical facts.

The teaching that cultural treatment has nothing whatever to do, either in the production—or perhaps the better expression would be the introduction—of canker, or in its suppression, is a question of greater import. There is no better known fact regarding the Potato disease than the so-called disease-proof qualities of some varieties, but it is equally recognised that these require a regulated treatment to preserve them so. Tomatoes present another instance, perhaps not so well marked. One might go a step further, and, if philosophically inclined, proceed to show that these diseases, if not the result, are at least the concomitants of cultivation under highly artificial conditions extending over protracted periods. They are the inevitable outcome of highly civilised plant life. But it is obvious that cultural methods are capable of modifying or, on the opposite, intensifying those

conditions; and as we find that wet and naturally cold soils, as well as those of a dry gravelly nature, produce a growth very susceptible of canker, so it is possible, by improving the latter class by the addition of good imported soil, and the former by draining, and in extreme cases surface-planting, to render canker at the least a less virulent disease.

I think there is reason to suspect that a tree continually underfed, or one growing in a soil naturally deficient in plant foods, to be peculiarly open to the attacks of canker. I have noticed in the case of old Holly hedges to which nothing in the way of feeding had been done, and also where bushes were growing singly in positions where roots of deciduous trees had robbed them of nourishment, that canker has proved almost fatal, and surface dressings have proved exceedingly beneficial, the cankered portions having of course been removed.

Growth, robust yet sturdy and well ripened, is what one desires for the production of high-class fruit, and the conditions which produce such growth appear to be those which also render the tree most largely proof against canker. Rank manures on this account are always to be shunned, and sound loam with proper chemical foods to be commended. The addition of iron to soils was some years ago confidently asserted to be a certain antidote, but though I have employed it with good results to the general health of trees, its effect in lessening canker cannot be said to be anything but problematical. Certainly it does not cure it. In the form of ferric sulphate or green copperas it forms a cheap manure, but the commercial article requires not a little labour to pound it sufficiently fine for use.

A method of at once stopping the progress of canker, and lessening its bad effects by means of excision of the portions attacked, might be more generally practised with always good results. If the bite has not been deep or widely extended the wound heals in a surprisingly short time, and even in bad cases where the wood has been eaten away to the "hard" a clean skin may be caused to grow along the edges. It is, however, necessary in order to secure good results that every bit of tainted wood be removed, and the cut be made smoothly with a sharp knife. The wonderful results achieved on various cankered trees by Forsyth at Kensington Gardens a hundred years ago, and which he attributed to the merits of a simple composition, were no doubt due to the care he took in eliminating every portion of diseased wood and bark. While much can be done by the knife in the removal of canker, it is also certain that careless pruning exerts a distinctly ready means of promoting its spread. This is especially apparent in the case of vigorous young trees, whole branches, and sometimes the entire tree, being lost through an injudicious wielding of the knife. There is only one thing to be done in such cases, and that is the excision of the cankered portions as soon as they are noticed. For the same reason all "snags" and dead spurs should be not merely cut off, but cut into living wood, by which means a skin is quickly formed over the wound. The evil effects of frost on Apple trees are, I think, perhaps less than is sometimes supposed. I do not know of an instance where canker has followed cracks in bark caused by frost.

It ought to have been more clearly indicated when noting the good effects of excising cankered wood, that the dead portions if left form a capital nidus for this insidious fungus to propagate its species. At present the plant is easily discovered in these portions by the dull red globular processes which mark an advanced stage of its life history. Hence the importance of at once removing the plants with its host, and also giving the tree an opportunity of healing its wounds.—B.

FORCING RADISHES.

EARLY and tender Radishes, if well coloured and quickly grown, are much appreciated at a time when salads generally are not plentiful. To secure them in this condition at an early period they must be grown in the mild and gently forcing temperature of a hotbed. French Breakfast and Wood's Early Frame are the two best varieties for early forcing.

The heat produced solely from hot-water pipes is not so good for this crop as that generated by a hotbed formed within a frame, or built specially with a frame on the top. A brick pit filled with fermenting material is the best for early crops, as the heat is not so readily lost, which is important. The materials for forming a hotbed should be composed of stable manure and leaves in equal parts. Shake out the manure in a heap, and add the leaves at the same time. Turn the heap once or twice, then place in the frame, treading it firmly.

A bed 3 feet thick will be of a bulk sufficient to produce a fairly lasting heat, but the height of the bed may be brought to near the glass, as the materials sink in the course of fermentation. On the surface of the bed place 4 inches of soil. Good garden soil, or old potting soil mixed with leaf mould or fine vegetable matter, is admirable for the purpose.

Make the surface level and sow the seeds thinly, taking a little care in distributing them, as under such favourable conditions every seed will germinate. Cover them after sowing with just enough soil to hide the seeds from view. Keep the soil moist, but this will be maintained

if the lights are kept closed and shaded until the seedlings appear. After that abundance of light is necessary, and air daily except in unfavourable weather.

Any appearance of crowding must be promptly prevented by thinning, but this must be done as soon as it is obvious that the roots will be thickly placed.—E. D. S.

ALLOTMENT AND COTTAGE GARDENS COMPENSATIONS FOR CROPS ACT 1887.

WHAT is supposed to be the first claim under the above Act has been made before the Croydon Bench by Mr. J. Cooper, of Carshalton, for £50 as compensation for crops, against Mr. Chandler, of Croydon. As the Act provides for the appointment of an arbitrator, the magistrates appointed one of their number, Mr. A. H. Smee, F.R.H.S., to deal with the case. As the arbitrator seems to have unlimited powers in procedure and as his award is final, the case is of interest to both owners and occupiers of small plots of land.

It may perhaps not be generally known that the Act in question provides that when the tenant of a cottage garden or allotment is compelled to quit his holding he shall be entitled, notwithstanding any agreement to the contrary, to obtain from the landlord compensation in money for crops, including fruit, in the ordinary course of cultivation, for labour expended and for manure applied after securing the last crop, for fruit trees planted with the written consent of the landlord, and for certain buildings, also erected under similar consent.

In the case under notice the land, about three-quarters of an acre, was sold by the plaintiff (Mr. Cooper) to the defendant (Mr. Chandler); then a written agreement was entered into between the parties by which the former owner became the tenant at a rental of 2s. a week, and this tenancy Mr. Chandler determined with a week's notice, which ended in July. Hence the action. Mr. Smee held his inquiry at the Croydon County Bench on Thursday last, and we take the following report from the "Croydon Advertiser":—

Prior to the case being opened, Mr. Smee said he had been appointed as arbitrator to the magistrates. He understood that this was the first case of the kind that had been tried in that court. He did not himself know any precedent for these proceedings, and he should be glad if the solicitors on either side could refer him in their experience to cases similar to this. To his mind it was very unfortunate that this application had not been made earlier, for at the present time they all knew that the crops would have ceased to exist, or had been considerably reduced in value by frost and other things. What he proposed to do, and what he hoped would meet with the approval of the solicitors, was to take item by item, and see the amount of good that had been under different specific cultivation. It seemed to him, looking at the Act, that he had to value the crops not as on a particular day, but as to the value when they would come to maturity. He would like to bring it to their notice that in connection with allotment ground he had sold to the Rural District Council, it was found necessary, by the requirements of the Allotments Act, that the tenant should be given notice to clear, and six months' notice was given. He had made it a practice to look round the allotments in the district every year between the 1st July and August Bank Holiday, and from his experience as horticulturist was able to judge of the state of the crops in the district, and he thought it would be a fair thing if he considered this claim on the basis of the average crops, unless the plaintiff could on the one side prove to him that his crops were superior to the average, and unless the defendant could prove that they were inferior.

Mr. Newnham (plaintiff's solicitor) said that as far as his experience went he could not refer the arbitrator to a previous case. In his view the crops should be valued as on the date of the determination of the tenancy as between the incoming and the outgoing tenant.

The Arbitrator said he proposed taking great pains over the case. He considered it important as establishing a principle. He took it that the Act meant that the man should have full market value of the crop.

The Clerk (Mr. Stayner) pointed out that it was unusual to have gardens or allotments at a weekly tenancy.

Mr. Newnham—Defendant gave a week's notice, and turned the plaintiff out at once. He allowed him no more time.

The Arbitrator—I cannot understand why it should be considered as a weekly tenancy when a man enters into a series of operations for the cultivation of land. He should not be expected to give up at any moment.

Mr. Newnham—Having given a week's notice, the landlord excluded the tenant from the ground and let it to someone else. He was not allowed to return to it.

The Arbitrator—I think I have to determine what the compensation should be for turning a man out in the most active time of the year, when he would be particularly occupied in the garden.

After some further discussion of technical matters the Arbitrator suggested that, as it was likely to be a troublesome case, and that he was bound to make some award, the parties should try to settle the matter among themselves without going further into the matter.

A short adjournment was made, but no agreement being arrived at the case proceeded.

After hearing evidence on both sides on the nature of the crops the Arbitrator said that when he had particulars of the claim he took them home and went through them carefully, and put down an amount which he thought was right. The only result of the inquiry would, if anything, be to make him increase that sum by £1 perhaps. He had gone into this case most carefully for the reasons he had given. He had spent a considerable time in horticulture, and he had endeavoured, as far as possible, feeling the great difficulty there was in estimating the value of crops which had perished and crops that had not been gathered and turned into money,

to arrive at an award which would be satisfactory to both. The sum he proposed was £16 10s., each side paying their own costs.

The money was at once paid.

It will be observed that though there was a written agreement (which was produced) of a weekly tenancy, it was of no effect under the Act; also it will be noted that while the Arbitrator took a broad, practical view of the case, he was not deceived by inflated values, and set, we think, a good and sound precedent.

THE USES OF HOTBEDS.

THERE are many purposes to which a hotbed may be put, including the forcing of Rhubarb and Seakale, sowing small seeds of vegetables and flowers, rooting cuttings of softwooded plants, and growing Cucumbers and Melons. Except for the purpose of forcing growth of Rhubarb, Seakale, Chicory, and raising seedlings of some early varieties of Cauliflowers, Mustard, Cress, Radishes, and Lettuce, it is fully early in the season to form hotbeds. The earliest hotbeds are best made in brick pits, as these will conserve the heat better than one built in the open air; indeed it will not be possible to maintain a good temperature for any length of time without lining the beds with fresh additions of fermenting material.

The materials for the construction of hotbeds must be collected, and then undergo a period of preparation before utilisation for the purpose in question. Undoubtedly the best materials are horse droppings containing plenty of long litter saturated with urine, and tree leaves, those from Beech and Oak trees being better than leaves of a softer character. These may be placed together during the present month, as opportunity permits, and eventually be well shaken out and mixed. They will require turning two or three times, and may then be formed into a bed. Horse manure heats rapidly and strongly, but the leaves tend to correct this. They not only subdue the heat, but prolong the heating power of the hotbed, hence their value when intermixed with manure is great.

Unless absolutely necessary, I would not recommend an open hotbed, that is a square bed of fermenting material with a frame on the top, for the first six weeks of the year, except where only a mild heat is required, such as for early Radishes or Lettuce, and forcing Mint. Within the confines, however, of brick walls, an early hotbed would be more useful because retaining heat longer.

Hotbeds are not needed so early in the year as formerly, owing to the facilities of obtaining a constant temperature by means of hot water pipes, but for produce that requires only a gentle heat and some moisture the hotbed is preferable. On the whole hotbeds are valuable adjuncts if there is convenience and material to form them. In most gardens several might be profitably employed during the months of March, April, and May. Half-hardy annuals may be sown during March in pans or boxes; cuttings of Lobelias, Petunias, Fuchsias, Coleuses, and similar softwooded plants will root readily in the genial atmosphere of a hotbed.

If the temperature is sweet and ranges about 65° to 70° choice seeds will germinate, but the same temperature must be maintained for the seedlings afterwards, so that they do not experience a check in their early growth. When a hotbed becomes half spent or partially exhausted it is an excellent place on which to sow successional crops of Radishes, Lettuces, or Carrots, to prick out Celery and seedlings of half-hardy annuals. In April hotbeds may be formed and seeds of Cucumbers, Melons, and Vegetable Marrows sown in pots. The two former to be planted on mounds of soil in other well heated frames, and the latter transferred to cold frames to harden for planting in the open with a little protection until the weather permits of full exposure.

When the heat of a hotbed and the sun combined give a temperature of 75° to 90° such plants as Dracenas, Indiarubber, and others may be propagated. A hotbed in March is useful to raise Tomato seedlings, but the after growth ought to be made in a drier and airier house or frame. The seed of Primulas will germinate in the genial bottom heat of a hotbed, and afterwards the young plants can make their first growth and become established prior to their continuing growth in a cold frame for the summer. Cuttings of Chrysanthemums intended for dwarf plants can be rooted in May or June in the genial temperature of a mild, half-exhausted hotbed.—E. D. S.

SPLITTING OF APPLES.—"A. D." (page 566, last vol.) is rather badly adrift in this question. In his endeavour to construct a theory he has begun at the wrong end with regard to the principles of heat and cold. Some years ago I was taught that water swelled when heated, not when cold, and practical proofs of the matter can be found in pipes bursting at the thaw following a severe frost, hot water circulation, steam engines and things, but these have not apparently entered into "A. D.'s" calculations. Possibly had "A. D." laid the fault with the shrinking skin instead of the swelling flesh, he would have been nearer the mark in such a case as he describes, but, I am not going in for theory manufacture. What a fascinating pursuit it is to approach the mysterious. But I always deny myself the luxury, in print at any rate, and it is a good old truism that circumstances alter cases, even of Apples splitting.—H. RICHARDS.

WATERING IN WINTER.

My first observation on the question on plants "damping" in frames and greenhouses in the winter will possibly take some persons by surprise, but its truth will be admitted by others of wider experience. It is this. Numbers of plants are ruined by the decay of their stems and the base of their leafstalks in winter through being kept too dry at the roots. The very fear of giving water, and the manner and time of giving it, create the evil that it is desired to avert. Applying just sufficient water to moisten the surface of the soil daily, and no more, is the worst practice that can be adopted, and the evil is aggravated if the water is given towards the close of the day.

To begin with, the whole of the plants in a collection never require water at the same time, and to give it to those that do not need it is to do them distinct and decided injury. This is an old story, but it is true, and it is better and more useful to tell it once again, and with emphasis, than to search for some novelty to express and record nonsense. Again, to give a uniform quantity of water to all plants, regardless of their differing conditions, can no more be defended than could the unheard of practice of making a weak and helpless child drink as much as a strong man engaged in exhaustive work. This method of giving support to plants and individuals is alike unreasonable, yet while it is often adopted in the case of the former, common sense rises in rebellion at the very suggestion of its application to the latter. Let the same common sense be exercised in giving support to plants, increasing or diminishing it according to the measure of their activity and exertions, and very different results will follow than from those accruing from an indulgence in the free and easy policy of treating all alike; for by this plan most or all must suffer sooner or later, some through being overgorged, others from starvation.

But to the question of damping from drought at the roots. It is in this wise. Give daily sprinklings, and what is the result? The soil is wet where there are few or no roots to imbibe the moisture, while down below, where the most active roots are established, there is no moisture to imbibe. What follows? Simply this: the plants will not die without a struggle, hence attempt to absorb through the stems what is denied them at the roots, and perish in their effort to prolong life, damping through the decay of the cuticle. This occurs the more quickly if water is given towards evening and the night temperature is very low, for dry roots and a cold moist atmosphere are a fatal combination. The remedy is obviously to reverse those conditions.

Plants in a growing state, no matter what they are, should no more be allowed to suffer from drought at the roots in winter than in summer. In nature plants and trees are not as dry as dust in winter, yet they do not damp off in well-drained soil from which water passes freely; but they enjoy the counteracting influences of a free circulation of air that periodically conveys the moisture from the surface, leaving the earth moist below. Moisture there does no harm provided it is not stagnant; nor will moisture in the soil in flower pots. Let the roots have what they need and not more than they need, while the surface is comparatively dry, and with a buoyant atmosphere and genial temperature there will be little or no danger of the decay of the stems or leaves near the surface of the soil.

"Yes," the puzzled novice may observe, "that sounds right enough, but how can we give water to plants without making the soil wet on the surface in our desire to keep the roots moist below?" It is not a question of momentary wetness of the surface, for that does no harm if water is given when plants need it, and only then, on the morning of a prospectively fine day, or when the air can be warmed artificially, and the top ventilators slightly opened for the dispersion of moisture.

Sharp currents of air should be avoided through the front sashes, these causing a chill to the plants by arresting the transit of sap. Anyone can have a conclusive example of this who may happen to have Vines in full leaf in frosty weather in March, the roots being in an outside border, and the stems encased in haybands, for he has only to remove a portion of the covering and expose a few inches of the stem of one of them to the frost and the leaves will speedily flag, no matter what the temperature of the house may be. Permit, then, no sharp wind to drive through the ventilators directly against plants in greenhouses in the winter. The air in a plant structure can be speedily changed through the top ventilators alone, the cold outside air sinking by its weight into the house and displacing the lighter, because warmer, air inside. Admitting air without a draught or sensible inrush of cold is the secret of successful ventilation.

To return to watering plants in greenhouses in winter. They should be examined every morning, and water as warm as the house given to those that are more or less dry on the surface, and those alone, passing all others, even if they remained wet for a week. But in this matter thought must be exercised, always remembering that a great mass of soil containing few roots may get drier with impunity, and even with benefit to the plant, than can a lesser bulk of soil containing many roots; or, in other words, a large plant well rooted in a small pot will take, and must have, more water than should be given to a small plant not well rooted in a large pot. If water is applied to the plants when the soil is in a state to require it, crumbling more or less when rubbed, it is very soon drier on the surface than it is below, provided sufficient be given to pass to the drainage; and it must be given to that extent, or the work will not be well done. It is well if not more than that is applied, especially in damp houses,

for a stream passing through the soil indicates success, rendering the air of the house moister than is desirable under the circumstances. Water should be used, not wasted. It should be given sufficiently, but not in excess, to plants that need it, and withheld entirely from those that do not require any. There must be no half waterings, no dabbings or dribblings, no spilling on stages or floors, and any that accidentally falls where it can do no good, but may do harm, should be promptly dried up. That is, as far as my experience goes, the way to water plants in greenhouses in the winter. They must not suffer through drought then any more than at any other periods, but at the same time there is great danger in forcing water on them when the soil already contains sufficient for their support during the twenty-four hours next ensuing.

A word on imported Camellias. Healthy-looking plants, set with buds, in small pots, have generally been grown in damp frames or moist pits, and the pots are usually filled with roots. If these plants are arranged on open stages in dry houses there is great danger in letting the soil get too dry before giving water. As a rule they are best stood on a close base, and damp rather than otherwise; for if dry air rises upwards, such as from hot-air pipes, and acts directly on the under sides of the leaves, the moisture is extracted from them too rapidly, the leaves curl and the buds fall. It is better to syringe them occasionally on dry days than to permit extreme transpiration; and on no account must the soil get so dry at any time as to shrink, even slightly, from the sides of the pots, or there will be no flowers. It is safer to err in slightly overwatering instead of underwatering these root-bound Camellias, but an opposite course will be safer in the case of plants with a limited extent of active roots in large pots.—J.

EXPERIMENTAL GARDENS.

SINCE the inauguration of County Councils that part of technical education known as horticulture, which should be of inestimable value eventually to the cottagers of England, has received in some counties special attention—we may notably mention the counties of Surrey, Kent, Essex, Worcestershire, Derbyshire, and Cheshire. We must not omit to mention also the excellent work the Duke of Bedford is doing in practical horticulture at the experimental fruit garden at Ridgmont. Where there is no stint of money and brains the results should be gratifying to everyone concerned, and of practical utility to every cultivator of the soil.

In addition to the above mentioned counties it may interest your readers to know that in the Isle of Wight something is being done to further horticulture from a practical point of view, and with that object in view the County Council has acquired a piece of land which was formerly a market garden in Newport, about 1½ acre in extent. This unfortunately will be much reduced in the near future by the erection of a free library and other buildings. Still sufficient ground will remain to carry out trials of fruits, flowers, and vegetables on a small scale, which should result in much good being done towards the development of horticulture in the Garden Isle.

A range of greenhouses has been built in which will be grown fruits, flowers, and plants for experimental and teaching purposes. In the south-east corner of the garden is a small rockery for a miscellaneous assortment of rock plants and Ferns. On the walls are trained trees of Figs, Peaches, Nectarines, Apricots, Cherries, Apples, Pears, and Plums, whilst against the piers are double cordon Apples and Pears.

In the open are varieties of many of the aforementioned fruits in bush, pyramid, half-standard, and standard form, a large bed of Gooseberries in thirty varieties, and also a bed of Red, White, and Black Currants in fifteen varieties. Raspberries are represented by thirteen, and Strawberries by twenty-five varieties respectively. Between the rows of fruit trees, which are about 40 feet apart, will be grown flowers and vegetables.

The past season has not been one of the most advantageous to a newly planted garden, yet under the circumstances the results have been most satisfactory. The primary objects of the garden are:—

- 1, To test the value of new fruits, flowers, and vegetables alongside the older varieties, also to ascertain their value for cropping purposes and the quality of their produce.
- 2, To teach by practical demonstration various horticultural operations. These I need not enumerate, as your readers are fully acquainted with them.
- 3, To illustrate forms of plant life, their habits of growth, and cultural requirements.
- 4, To test the effects of manuring and non-manuring, and the effects of different manures in varying quantities on different subjects.
- 5, To test varying methods of treatment on similar varieties of subjects with an object of ascertaining information for practical use.
- 6, To test the effects of various fungicides and insecticides.
- 7, To show the advantages of good cultivation over the bad and indifferent.

The latter object has been fully shown during the past season. The trees, which were mulched after planting, and received during the summer periodical syringings, made free growth and produced healthy foliage, whilst those left to take care of themselves were stunted in growth with small and thin foliage.—S. H.

LÆLIO-CATTLEYA DOMINIANA.

YEARS ago, before the parentage of this charming hybrid had been really proved, it was recognised as one of the finest Orchids in cultivation; and latterly, when more care was taken in keeping records, and in choosing good varieties of the separate species as parent, the results were still more satisfactory. Quite recently I saw a very pretty form of it, and even now, with the immense number of fine hybrids, we have few to surpass it. Its relation to that superb *Lælia*, *L. purpurata*, is shown in its beautiful colouring, while its variability is equally and obviously due to the same relationship.

LÆLIA ALBIDA SULPHUREA.

This is a very attractive variety of a choice and beautiful little *Lælia*. By no means rare in the usual acceptance of the term it will in all probability be rarer as time goes on, many hundreds of plants being frequently imported, only to flower respectably for a time and then to rapidly pass out of condition and become of no value. If any reader of the *Journal of Horticulture* has been successful with this variety or the type he would be doing a service in recording his methods. By successful I mean over a number of years, not less than six or seven at the least.

CÆLIA MACROSTACHYA.

Not many species are included in the genus to which this pretty Orchid belongs, and it is perhaps the best known of all. From a roundish leafy pseudo-bulb it throws up an erect spike of silvery rose blossoms, each with its attendant white bract, and though the individual flowers are small they are charming in the aggregate. A good place for it is the coolest part of the *Cattleya* house, or where *Lælias* of the anceps type thrive. It likes a moderately good compost, consisting of peat and moss, with a little loam for strong plants.

The pots must be well drained, as during the time growth is active an abundant supply of moisture must be allowed. After this a short and sharp dry rest is necessary, or no flowers will be produced. I have known plants to grow for eight or nine years without showing a single flower spike. I rest it in quite a cool house—much cooler, indeed, than the majority of Orchids care for—and find that a somewhat rapid change to a warmer house usually induces the production of abundance of spikes. The flowers are produced at various seasons, but mostly in autumn and early winter. It is not often imported, though said to be common in various parts of Mexico, whence it was sent to Chiswick in 1841.

CYMBIDIUM GIGANTEUM.

This is a useful winter-flowering species when really well established, but often for the first few years in this country it is rather shy. It is a capital grower, in habit similar to *C. Lowianum*, but the flowers are quite distinct. Fortunately, too, for the health of the plants, the latter do not last as long as those of the better known kind. These, when allowed to remain, as they will do for months at a stretch, are a great strain upon the resources of even the strongest plants, and will often kill weaker specimens outright if the practice of leaving the flower is persisted in.

With *C. giganteum* the flowers, though very lasting, do not remain fresh quite so long, and therefore strong plants are uninjured, even if allowed to carry the blossoms until they fade. Both need exactly the same treatment, and are attacked by the same insects. They like a cool moist house, and it does not matter whether this is devoted entirely to Orchids or not. It often does well in a cool fernery, and I have a very large specimen now in flower in such a house. Good fibrous loam, peat, and chopped sphagnum make a capital compost for it, and the pots should be large and well drained. *C. giganteum* is a native of the Himalayas being found at considerable elevation.

LÆLIA AUTUMNALIS.

Mr. J. Barker has a very interesting note on this species, and I quite agree with him as to the necessity for plenty of fresh air and a buoyant atmosphere. Although at times we meet with plants doing well in more heat and moisture, it is quite certain that the growth can hardly be too well consolidated and hardened as it is grown, the plants then being able to withstand any slight check—unavoidable in some cases—that may happen.

I also agree that if it were possible to keep the temperature at the figure your correspondent names it would be an advantage, but this species and other Mexican *Lælias* require ample light, as he points out; and if this is allowed, it is quite impossible to keep the temperature down to 65° on a hot summer day. It may be managed by very heavy shading and keeping the house close, but not other-

wise; and I have on many occasions proved that sun heat, when ample air is allowed, does not harm these plants in the least. It is only when accompanied with considerable moisture and with insufficient ventilation that any harm accrues. I only mention this point to prevent any amateur readers attempting to keep the temperature down by the means indicated, as it does far more harm than good. —H. R. R.

LÆLIA GOULDIANA.

HIGHLY coloured flowers are doubly appreciated at this dull season of the year, and a specimen of *L. Gouldiana* is an object of beauty, of which the cultivator can well feel proud. The plant will succeed under the same conditions as *L. autumnalis*, from which it is supposed to be a natural hybrid. When in flower great care should be taken that no water is allowed to touch the flower, or decay will set in. I find no difficulty in cultivating this species with the above-mentioned one, only not being such a vigorous grower much less water will answer its requirements. The flowers are useful where buttonholes are a requirement, not being so large as *L. autumnalis*. The flowers, like those of the best forms of that variety, are of a deep rosy purple colour.

SOPHRO-CATTLEYA CALYPSO.

True bigeneric hybrids are, even at the present time, scarce, and the above mentioned is described by the late Professor Reichenbach as a gem, and is an acquisition to anyone fortunate enough to secure it. The plant is perhaps best described as a miniature *Loddigesi*, with pseudo-bulbs about 4 inches high; the flowers (fig. 3) are about 3 inches

FIG. 3.—SOPHRO-CATTLEYA CALYPSO.

in diameter, petals broader than the sepals, of bright rose colour toned with scarlet, which has a wonderful effect on the whole flower. The lip is distinctly three-lobed, the side lobes roundish, convolute over the column, slightly reflexed towards the apex, pale lilac externally, and on the inner side creamy white bordered with amethyst purple at the anterior margin; middle lobe broadly oval, undulate at the margin, crimson purple; column white, stained with purple at the apex.

This plant was raised by Messrs. J. Veitch & Sons, and shown by them December 13th, 1892, when it received a F.C.C. I find it succeeds admirably in a cool intermediate house, under the same conditions as *Lælia præstans* as regards compost, but great care must be used in applying water while the young growths are in a green state, or they are apt to turn black and die. The parentage of this gem is *Sophranitis grandiflora* × *Cattleya Loddigesi*.

CYPRIPIEDUM EURYADES.

Another section of this most useful family, in which the hybridist has undoubtedly improved both parents, is the one in which *C. Lee-anum* and *C. Boxalli* comprise the parentage. The first record we have of this cross is in the year 1892, when Messrs. J. Veitch & Sons showed a plant and received an A.M. for a plant under the name of *C. Hera*; again, in the same year, the Chelsea firm showed *C. Adrastus*, followed by *C. Euryades* in 1896. It is to be expected from such a cross, and one parent a hybrid, that there will be a wide range both in colour and size in the progeny, and it is useless to describe one or the other.—J. BARKER, *Hessle*.

DENDROBIUM SPECTABILE.

THE treatment I find to suit this New Guinea species is quite different from that to which the Indian *Dendrobiums* are subjected. My

success with this and other species from that region is attributable to the fact that we never allow the plants to become dry, or permit violent fluctuations in the structure. On the contrary, we strive to maintain a moist genial atmosphere, the degree of warmth varying with the external conditions. From early in November until the end of February the plants are afforded all the light and sun possible, but during the remaining portion of the year shading is resorted to, or the plants will soon be disfigured and probably never recover. *D. spectabile* will not stand a cold, damp air; in foggy weather during November and December let there be sufficient warmth in the hot-water pipes to make the house feel quite comfortable on entering.

Anyone who grows the usual occupants of the stove to perfection (except *Crotons*, because the last named need all the sun we get) should be able to cultivate the beautiful species under notice hung near roof. If the structure is a span-roofed one, running east and west, hang the plants near the glass on the north side during the summer and remove them to the south side for the winter months. In potting the plants use very small Orchid pans, only just large enough to accommodate the roots. Employ the best Orchid peat fibre broken into small lumps about the size of Walnuts. We use only one layer with heads of live sphagnum between the lumps of peat. Let both pans and crocks be new, as these plants are very impatient of root disturbance. For these plants I have a most decided preference for square shallow teak baskets, as the roots will cling to the wood, and should the compost become sour or the crocks green and mouldy the roots may be picked out and the plants washed in tepid water. The crocks can then be renewed, also the peat and sphagnum with a few small crocks or charcoal intermixed, but not sand. It is most important to remember that the New Guinea Orchids cannot withstand cold draughts, and, therefore, should the sun be so bright as to run up the temperature too high, and there is a cold wind, only open the bottom ventilators on the lee side of the structure.

Strive to keep the sphagnum continually growing all the year round, as it forms an excellent guide as to watering. When the moss begins to look dry apply water 10° higher than the temperature of the houses. Some growers are under the impression that New Guinea Orchids must have a high temperature, but this, I think, an error that is likely to be followed by disastrous results. Our plants are kept at the present time in a night temperature of 60° to 65° , rising to 65° and 70° by day. This will run with sun heat to 85° or 90° , and must be accompanied by ample atmospheric moisture. *D. atrovioleaceum* thrives under precisely similar conditions. I hope to send notes on other species from Northern Australia, Queensland, and New Guinea for insertion in an early issue.—F. J. THORNE.

[We commend the above notes to the attention of all Orchid-loving readers of the *Journal of Horticulture*, as Mr. Thorne's success with what are usually considered "difficult" Orchids is remarkable. For some years the Sunningdale Park plants of *Epidendrum* (*Diacrium*) *bicornutum* and *Dendrobium atrovioleaceum*, to cite only two examples, have been the envy of many growers. And there can be small wonder at this, for where the majority of these plants merely exist, at Sunningdale they luxuriate. It is to be hoped that the cultural details given, with those promised for a future occasion, will be of material assistance to growers whose efforts have not hitherto been crowned with success.

On Christmas eve we had the pleasure of seeing Major Joicey's collection of Orchids, and the inspection was a most enjoyable one. Notwithstanding the heavy fogs that have been experienced of late and the exceptional fluctuations in the weather, there is a very beautiful display of flowers in several of the structures. *Dendrobium spectabile*, to which special prominence is given in the above communication, is represented by three plants all in good health, and one of which is producing the flowers that have received such attention during the past few weeks. Of *D. atrovioleaceum* there is a much larger stock, producing in all upwards of fifty spikes of flowers. Knowing this it need not be said that the plants are in splendid condition. Side by side with these is the chastely beautiful *D. Johnsoniæ* (*D. Macfarlanei*), the flowers of which are singularly attractive at this period of the year.

More brilliant in colour and entirely different in form are the blooms of *D. bigibbum*, which for Christmas time is absolutely essential to a complete display. Still further diversity is afforded by the more modest *D. aureum*, and the ever appreciated *D. phalaenopsis Schröderiana*, with its brightly coloured and abundant flowers.

Not that *Dendrobiums* form the sum and substance of the display. Such is by no means the case, for the *Calanthes* alone would make a show. There is not an immense number of plants, but each one carries splendid spikes of perfectly formed and well coloured flowers. One of the finest spikes had open on it at one time three dozen flowers, not, of course, counting the unexpanded buds at the apex. Then there are *Cymbidiums* rapidly developing, with many *Cypripediums* and *Lælias* in full beauty. Of the latter a richly coloured form of *autumnalis* and a plant of *L. a. Stella* were most conspicuous. Others, too, were there, but more cannot now be said of them or of the excellent health

of the hundreds of plants that are not at present adding to the glory of the display with their flowers, but which will in their turn do much to maintain the high repute in which Major Joicey's Orchids are held in the world of horticulture.]

LIVERPOOL NOTES.

AT ALLERTON BEECHES.

WHEN visiting the handsome residence of Henry Tate, jun., Esq., on a mid-December day I knew that I should see many choice Orchids in flower, for the collection is rich in good things, but my anticipations were more than verified at the bright array of flower which met my eyes. Splendid specimens of *Oncidium varicosum*, *Rogersi*, and *tigrinum*, *Lælia anceps* in variety, *Cypripediums* of the montanum section, *insigne*, *Chantini*, *albo-marginatum*, *punctatum violaceum*, *Leeanum*, all perfect in health and beautifully flowered, with *Lælia albida* and many others, were especially inviting. Curious and decidedly pretty was *Cypripedium insigne bisepala*, Tate's variety, a well flowered plant in which the sepals are arranged above and below, every flower being perfect in character. It was imported in what was apparently a clump of seedlings.

The cool house was a picture of healthy growth, several plants being in flower, whilst *Odontoglossums* *Chestertoni*, *Alexandrae*, *Andersonianum*, *radiatum*, and many others too numerous to mention, were developing massive spikes. The boat-shaped raft of the somewhat difficult *O. coronarium* brought vividly to mind what I had seen of it, and how much may be again expected. *Masdevallia Veitchi grandiflora* added colours all its own.

Orchid-hybridising has been carried out most extensively for many years, but as yet only few have opened to satisfy the patient watchers. However, there are sufficient to delight everyone, the variety from the same seed-pod being worthy of note. *Cypripediums* *Sirdar* and *Cromer*, from *Boxalli atratum* \times *nitens superbum*, are both very fine, but quite opposite in colour. *Cypripedium tenebrosus*, a grand flower of a rich purplish shade, looked regal; whilst *C. allertonense*, a fine, bold flower from *villosus* \times *bellatulum*, had the latter manifested in the dorsal sepal. More than a score of others were flowering for the first time, and the hundreds of seedlings raised by Mr. Osborne during the past five and a half years in which *Rothschildianum* crosses are abundant were in every stage of healthy growth, and showing for flower. Three dozen *Lælio-Cattleyas*, none of which have flowered, but the majority of which will do so next season, hang from the roof. What delights lay stored up in the vigorous stock! and how little the impatience of any human being could help forward their time of flowering!

The Orchids were not the only bright attraction, the warm conservatory being filled with a gorgeous display of *Poinsettias*, *Salvia splendens*, *Begonia Gloire de Lorraine*, *Azalea Deutche Perle*, the latter specially well grown, and other seasonable flowers. The stoves contained a selection of everything rich and good, the scrupulous cleanliness and vigorous appearance of everything being a tribute to Mr. C. Osborne and his staff, and an unfailing pleasure to Mr. Tate. Yet, with it all, a feeling of sadness must pervade many Liverpool people at the thought that Mr. Tate is soon about (owing to business) to remove to London.

AT ELMHURST, AIGBURTH.

There are several good collections of *Eucharis* in our neighbourhood, but none that commands greater attention than those grown by Mr. J. Harrison for Mrs. W. G. Bateson at Elmhurst, Aigburth. *Eucharis* form a specialty of Mrs. Bateson's, and she certainly has good reason to be proud of her splendid collection and the care evinced for their welfare by Mr. Harrison. The house in which they are growing is span-roofed, underneath the central stage being a tank of water, with 4-inch pipes running through. This moisture arising Mr. Harrison thinks the cardinal point as regards sound root action, the syringe playing its important part on the top growth, and I should be sorry to question the statement, for the twenty-four plants, in pots ranging from 12 to 22 inches, bore unmistakeable signs that the treatment was perfectly sound. Drainage is an essential point upon which Mr. Harrison insists, the pots being half filled, and the bulbs potted in good fibrous loam three parts, with charcoal and sand. Plenty of water in summer, but great care in winter is exercised. Soot-water gives the tone to the leaves, and the old-fashioned shading of flour made to the consistency of cream is still adhered to.

Mr. Harrison is no believer in periodical potting. The plants have this season been potted for the second time in thirteen years. The mite is unknown. Their flowering is somewhat late, but spikes developed and hundreds to follow must be a source of delight to Mrs. Bateson, and a deserved warranty for skill to the grower. *Pancratiums* are equally well done.

Fine indeed must be the plants likely to supersede the old *Pyrus japonica*, a splendidly berried plant, 30 feet by 18 feet high, growing against a stuccoed wall, being ornamental nine months out of twelve. It is altogether a fine and well-kept garden, and other notes may come in their season, for Mrs. Bateson loves her garden for all it is worth.—R. P. R.

EMIGRATION.

It is not often we receive two letters by the same post from gardeners ("D. G." and "H. C.") seeking advice as to their prospects of gaining a better living in distant lands, than they can obtain in their own country. No questions are so difficult to answer, because of the enormous differences in the health, strength, and capacities for perseverance of the men themselves. Some can adapt themselves to unforeseen circumstances much better than others, and one will forge his way through obstacles to which another would succumb.

Then there is the element of chance or luck—call it what you will—to exert an influence, as one man may meet with opportunities that another happens to miss; and again, one may make much better use of his chances than another. This is the case at home and abroad. That some men in the gardening ranks seem to have been the favourites of fortune none can deny; but all the same, we suspect that far more who enjoy comfortable homes, do so as the result of their own good judgment, industry, and perseverance. They worked as heartily in small gardens as in large, however low their wages, and thus established a character for competency and trustworthiness. Such men usually find opportunities for advancement; but though the waiting may be wearisome, they do not "throw themselves out" in a moment of haste or despair. They are men with a motto—"Do what is right, and never despair."

It is much the same at home and abroad, though longer hours of harder work is the rule over the water than in the old country. We deplore the plethora of thoroughly good, useful, and industrious gardeners, who find it hard to win in the battle of life; and we are not over-enchanted with the fashion of the times to further overburden the ranks by making more "on paper"—men or women—in colleges and schools. Some of these can scarcely fail to be other than dilettantes, and therefore destined to reap disappointment, of which, in fact, a foretaste is in certain cases already experienced.

As regards emigration, it is entirely speculative—at least in the absence of arrangement for employment at a given destination. We are glad to know of British gardeners who have done and are doing well in other lands, though perhaps as many have failed in the object of their hopes, though some of these have found employment in other callings, more or less to their satisfaction. Those who succeed in the States or Colonies write hopefully, a few glowingly; but those who do not have a different tale to tell, of which we can give an example in the following lines:—

"Come, boys, I have something to tell you;
Come near, I would whisper it low—
You are thinking of leaving the homestead—
Don't be in a hurry to go!

"You talk of the mines of Australia—
They're wealthy in gold without doubt;
But, ah! there is gold in the soil, boys,
If only you'll shovel it out.
The mercantile trade is a hazard,
The goods are first high and then low;
Better dig the old soil a while longer—
Don't be in a hurry to go!

"The great busy West has inducements,
And so has the busiest mart;
But wealth is not made in a day, boys—
Don't be in a hurry to start;
The bankers and brokers are wealthy,
They take in their thousands or so—
Ah! think of the frauds and deceptions—
Don't be in a hurry to go!

"Home soil is the safest and surest,
The orchards are loaded to-day,
You're as free as the air of the mountains,
And monarch of all you survey.
Better stay on that soil a while longer,
Though profits come in rather slow;
Remember, you've nothing to risk, boys—
Don't be in a hurry to go!"

We do not know whether or not those lines were written by one of the several men who have tried emigration, and found it wanting; then struggled their way back to the land of their birth, and made for themselves contented homes. The lines are not inserted for the purpose of dissuading the enterprising, but we should like to feel that the emigrant gardener who has "nothing to go to," has enough money to "keep" him in the new land for at least six months (and look well after it), with a reserve to pay his passage home again.

FRUIT TREES IN SOUTH AFRICA.—Fruit trees and shrubs, while well known and appreciated in South Africa, are not offered for sale, according to Consul-General Stowe of Cape Town. A representative of a United States nursery assured him that he sold more trees in a period of eight weeks than he could have sold in the United States in twenty-four weeks. Fruit of nearly every variety can be cultivated in South Africa, but the growers must, of course, be educated. As there are no frosts the insect enemies are very destructive, but these can be held in check by the same means employed in the United States. American fruit and ornamental trees, chemical preparations, spraying pumps, can be introduced into that country with profit.—("American Agriculturist.")

THE YOUNG GARDENERS' DOMAIN.

ALLAMANDAS.

AMONGST the many stove climbers, I think nothing looks more charming during the summer months trained over the roofs than Allamandas, with their glorious foliage, intermixed with magnificent yellow flowers. When properly grown they are of fairly easy culture, but like most stove climbers they require considerable attention during their growing season. With care Allamandas may be had in bloom four to five months during the summer. In many stoves they are planted in places built for the purpose, but they may also be grown in large pots with equally good results.

When the plants have to be restarted after their season of rest they should be pruned back to within three to four eyes of the last year's growth; this ought to be done just when the buds begin to swell, but potting should not be done for a fortnight after pruning. In the meanwhile, however, the soil can be prepared. The following mixture will suit them admirably:—Good fibrous loam three parts, peat two parts, with the addition of decayed cow manure one part and a sprinkling of coarse sand. When potting every care ought to be taken not to damage the young and tender roots. The pots must be clean and well drained, as during the growing season they require an abundance of water. As the growth extends more attention will be required in tying and stopping, until the grower thinks enough good growth has been made to furnish the roof. Plants growing in pots require more feeding than those in borders, therefore at every alternate watering a little liquid manure may be given, and will be found beneficial, both to the growth and the flowers.

The Allamanda is also one of the most telling plants in the exhibition tents, as we often see grand specimens shown by the leading growers. These are grown on balloons with treatment similar to that already advocated. The chief point is to get the growth well divided over the balloon so as to allow the flowers to lie on its foliage. The plants must be kept well up to the glass, but as the flowers begin to open they should be slightly shaded. Some persons prefer to hang paper over them, but I consider a slight coating of shading over the glass safe at this point. If required for showing purposes the plants should be gradually hardened by removing them into the greenhouse quite a fortnight before the date of exhibition, for if removed too soon they are apt to be injured, and soon lose their foliage and flowers.

During the growing period a moist atmosphere is essential, and they should be syringed twice a day, this not only being beneficial to the growth but also for keeping the stock free from any insect pests, of which I think thrips are the most troublesome; and if once this enemy gets established it cripples the foliage and growth very seriously. The next important point is the resting and drying off, which should take place in October, therefore water should be gradually withheld until the foliage is down, but the growth must not be allowed to shrivel, or much damage will accrue to the buds.

There are many varieties of Allamandas, including Hendersoni, nobilis, Schotti, and grandiflora. The latter I have found more delicate than the others, therefore I would recommend equal parts of peat and loam, with an extra quantity of coarse sand. Many growers, I understand, have discarded this grand variety owing to its delicate constitution, but I think when properly grown it surpasses all the others for indoor decoration. Yet one more useful variety can be added to the list—namely, Williamsi, which, of late, has been freely used for grouping.

It is now necessary to refer to propagation, and I will describe the system I have found most satisfactory. After the old plants have been cut back, potted, and young growth advanced, say 4 to 5 inches in length, take as many as are required with a heel of old wood, and insert the cuttings singly in small 60-pots. Place a small hand-light on a hotbed in which the cuttings may be plunged, and by keeping a fair amount of moisture over them they will root quickly. As soon, however, as roots have formed they should be taken out and kept well syringed, potting as they require it in very sandy soil. No doubt there are other methods of rooting stock, while the plants may also be grafted on nerifolia. I have only noticed one grafted plant, which is supposed to have been worked twenty-five years ago. Every season it flowers profusely. It is grown in a pot, and every February it is turned out, the ball reduced, and the roots cut well back with a sharp knife before repotting.—W. L., King's Weston.

A BOOK FOR THE HOME.—An excellent and useful little work is "Holloway's Almanack and Family Friend," and coming, as it does, from one who has done so much for education (as witness that magnificent Institution the Royal Holloway College, at Egham), it may be relied on as an acceptable gift. It is issued free of cost, but its enormous popularity is not due to that fact alone. A copy of the issue for 1900 is to hand. It is full of excellent pictures. Besides a mass of information, which makes the almanack useful as a reference book, it contains a series of illustrated articles on the old customs of many nations. Every copy also carries with it a railway insurance policy of £100 for the whole of the year 1900. The little book is sent free by Thomas Holloway (the proprietor of Holloway's pills and ointment), 78, New Oxford Street, to anyone who sends one half-penny stamp for postage.

HARDY FRUIT GARDEN.

Preparing Soil for Planting Fruit Trees.—Thorough and complete preparation of the soil should always precede the planting of fruit trees, especially choice varieties. It is, however, waste of time and space to plant other than the best varieties of any kind of fruit tree. Some of the best succeed, nevertheless, better than others. These must be noted by observation or inquiry in the neighbourhood, or varieties about which there are doubts may be tested by planting and growing a few before establishing many.

Whether planting a large plot or inserting only a single tree, deep working of the soil is essential. A square plot of ground intended for fruit ought to be prepared in the following manner:—First divide it into two equal parts. At the end of one of these divisions take out a trench two spits deep, and 2 feet wide. Wheel the soil thus taken out to the same end of the corresponding division. The first spit of the next trench ought also to be wheeled away. Break up the bottom of the first trench well, and add some decayed manure if the soil is very poor, as it most likely will be. The second spit of the second trench may then be turned over upon it, also the first spit of the third trench. This method admits of the layers of soil being retained in the same position as formerly, thus insuring that the best soil is not buried and the worst brought to the surface. The work proceeds in this manner to the other end of the first division, when the first spits of the next division are used to complete it.

Finally a finish can be made at the end where the soil is placed. Positions for isolated trees must be prepared by excavating a circle 6 to 8 feet in diameter. Throw out the two spits, break up the bottom, and return the soil. If planting is to be done immediately the ground should be firmed by treading, but this must be done before rain falls, or when the surface is quite dry.

Planting Fruit Trees.—Although autumn is the best time for planting, yet trees will succeed well if they are planted in the course of the following weeks in dry, mild weather. The holes for the reception of the roots must be prepared wide and shallow. The trees ought to have healthy fibrous roots, and these must be preserved from injury by not exposing them long out of the soil. If the trees are growing in nursery quarters which are handy to the site for planting they should not be lifted until the position for planting them is ready. When procured from a distance lay the trees in moist soil as soon as received, and should the roots have become very dry plunge in water to plump up the tissues. Prune away all damaged parts. In planting spread the roots out to their full extent, the best plan being to form a slight convex mound of soil and distribute the fibres over it, a layer at a time. Sprinkle fine soil over the roots from the stem outwards, so as to secure the placing of the fibres in one direction. The next layer may then be spread and treated in the same way, the uppermost roots being covered with 4 inches of soil. Stake standard trees at once to prevent strong winds disturbing the roots, and mulch with 3 inches of littery manure.

Pruning Pyramid and Bush Apples and Pears.—If the main branches are sufficiently wide apart so that there is no crowding in summer, the winter pruning will resolve itself into shortening back the side shoots to one or two of the lowest buds. Where, however, old spurs have extended to an undue length it will be advisable to gradually shorten them, or remove altogether a few clumps in order that the rest may be disposed more thinly, and thus receive in better measure the benefits of light and air. A mistake often made in the training of these forms of trees is originating too many branches. None should be nearer together than a foot, as the subsequent side growth duly shortened each summer and winter will occupy much of the intervening space.

Pruning Standard Fruit Trees.—The simplest and best manner of pruning standard trees is to thin out the branches where they are too thickly placed or interlace with one another. A few years of neglect in pruning will soon produce a quantity of unnecessary wood, but trees rightly managed from a young state do not need much annual pruning to maintain them in good condition. Shortening the branches is altogether bad practice, as it induces the formation of more wood, which crowds the trees. Removing branches entirely will not do so, provided growths that may issue from near the cut parts are promptly rubbed out the following spring.

Pruning and Training Morello Cherries.—The growths of Morello Cherries are slender, and fruit is best produced on the wood which was made the previous year. The young shoots are, as a rule, freely produced, therefore a selection of the best must be made when pruning and nailing in to walls or tying to trellises. Both wood buds and blossom buds are produced on the shoots, but it may happen that all the buds on a shoot will be blossom buds except the terminal bud. Such shoots must not be shortened, as wood growth beyond the fruit is essential to perfect the latter. As a rule, however, the basal buds on

fruiting shoots are wood buds, and from these will proceed the new growths the next season. It may be necessary to prune away the last season's fruiting shoots now, though this ought to have been done immediately the fruit was gathered. The best young growth available must take the place of this, disposing all not less than 3 inches apart equally over the trees. Shoots inconveniently long may be shortened, but it must be to a wood bud. A limited number of growths that are not wanted for laying in at full length may be shortened to form spurs.

FRUIT FORCING.

Cucumbers.—Young plants coming into bearing should not be over-cropped, and they will be assisted by removing staminate as well as superfluous pistillate flowers as they appear. Plants in bearing will require to be examined at least twice a week, removing all weakly and exhausted shoots, reserving as much of the young growths as there is room for them to expand their foliage, overcrowding tending greatly to disaster, inasmuch as it must end in denuding the plants of a large extent of foliage. Stop the shoots at one or two joints beyond the show of fruit, allowing young plants more freedom, yet keeping the trellis evenly covered without overcrowding. The temperature at night should be 65° to 70°, 70° to 75° by day artificially, with a rise of 10° or more from sun heat, admitting a little air at 80° if the external air be moderately warm and soft, but if cold and sharp it is better to allow the temperature to advance a little higher than admit too much dry cold air, even when the sun is powerful. Close early in the afternoon, so as to utilise the sun heat, a temperature of 90° to 100° from that source being beneficial rather than otherwise.

Root action will be encouraged by light top-dressings of turfy loam and sweetened horse droppings in equal parts, sprinkling a little of a mixture of superphosphate three parts, nitrate of potash (powdered) two parts, and soot five parts, mixed, over it occasionally. Water or liquid manure should be supplied as required, but avoid excessive supplies, and be moderate in damping down and syringing at this season. Sprinkling the floor and other surfaces in the morning and afternoon with light syringing on very fine days will be sufficient.

Where winter Cucumbers are not grown, or the supply from April forwards is obtained from frames, seeds should now be sown to raise stock for planting next month, either in houses or manure-heated pits or frames; the fermenting materials for the latter should now be in course of preparation for making up the beds. If no convenience exists for raising the plants a bed of fermenting materials should be made up forthwith, the seed to be sown as soon as the bed affords a suitable temperature of 70° to 75° top heat, and 85° to 90° bottom heat. Plants from this sowing will be suitable for house planting, also pits and frames, to afford a supply of fruit from about the middle of April through the summer.

Peaches and Nectarines.—*Earliest House.*—The trees started last month are advanced in blossoming. When the flowers are fully expanded the night temperature should be maintained at 50° to 55° in mild weather (5° less when the weather is severe), 55° by day as a maximum in severe weather by artificial means when the sky is overcast, 65° by day from sun heat, and if the air be mild a few degrees more may be allowed with free ventilation. Syringing the trees must cease when the blossoms show colour, but a genial atmosphere should be secured by damping the floor and border in the morning and early afternoon of bright days, having recourse to an occasional sprinkling of such surfaces only in dull weather. Ventilate freely when the external conditions are favourable, and when the pollen is ripe choose the warmest and driest part of the day, preferably before or within an hour of the sun passing the meridian, for aiding its distribution by shaking the trees or trellis, or taking a camel-hair brush or feather and gently applying the pollen to the stigmas. If there be a deficiency of pollen of any variety it may be taken from those that afford it plentifully and applied to the stigmas of the flowers sparsely furnished with that essential of fertilisation and securing of a good set of fruit. The inside border must not be neglected for water, but avoid making the soil sodden by needless applications, especially of liquid manure, and afford sufficient protection to the outside border for the exclusion of frost.

Second Early House.—This is the first in most establishments being planted with trees of Hale's Early, Stirling Castle, Royal George, or Dymond Peaches, Rivers' Early, Lord Napier, Elruge, or Humboldt Nectarines to afford ripe fruit at the end of May or early in June, and should now be started. Damp the trees and house two or three times a day, but the former must be allowed to become fairly dry before nightfall, and in dull weather the syringing should be omitted, or had recourse to occasionally only. Turn the heat on in the morning so as to secure 50° through the day, ventilating at that temperature and allowing it to rise from sun heat to 65° with free ventilation. Sufficient fire heat at night to maintain a temperature of 40° to 45° will bring the trees on quite fast enough. The inside borders must be brought into a thoroughly moist state by repeated waterings if necessary, but where the roof-lights have been removed water will not be required until the fruit is set and swelling freely. The outside border should be protected with litter, a covering not to heat but to prevent chill from snow and the soil being frozen.

Later Houses.—These should be put in order forthwith, and if any trees are swelling their buds more rapidly than is desired, a covering of mats over the lights will prevent the temperature being raised by

sun heat to a great extent, and the flowering will be retarded considerably. Where the roof-lights have been removed the buds are as yet quite dormant, and the lights may remain off until the time arrives for starting the trees, or in case of late houses until the buds commence swelling. Pruning may then be effected and the lights replaced, which will not be required until the end of February, or later.

THE BEE-KEEPER.

CHANGING THE ASPECT OF HIVES.

WITH the opening of another year, whilst all is quiet in the apiary, steps should be taken to change the aspect of the hives where it is considered necessary to do so. It is a matter of opinion which is the best position for the hives to occupy. If it was a matter of choice we should prefer a south-west aspect to any other; but as we have stated in previous notes, there is really little difference in the amount of honey stored in hives placed in various aspects.

It is doubtless an advantage if the bees commence working early in the morning. This is to be observed more particularly during the early spring months when breeding is going on apace. The bees will then leave their hives much more readily if the sun strikes directly on them than if they are shaded.

As bearing on this question we may mention a fact that came under our notice. On Sunday the 24th ult. the sun was shining brightly for three hours during the middle of the day. The temperature was only a few degrees above freezing, but from all the hives placed in a south-west position the bees were taking a welcome flight reminding one of spring. There being little snow on the ground at that date the majority of the bees returned safely to their hives.

If bees have to be removed several miles by road or rail it will be an advantage to delay the operation till spring, as at this season, whilst the temperature is low, the bees are in a state of stupor, and are closely clustered in the middle of the hive. The jolting in a cart, however carefully they may be packed, will cause many of the bees on the outside of the cluster to fall on to the floor board, where they will soon become chilled, and be unable to return to the cluster.

STANDS FOR HIVES.

Before arranging the stands for the hives it will be an advantage to bear in mind the convenience of working the various colonies during the busy season, as much will depend on the careful manipulation of the bees whether success or failure has to be chronicled after another year's experience. One of the greatest mistakes that is made when hives are being placed in the position they are to occupy is to place them close to a wall or fence, so that it is impossible to get at the back of the hive whilst manipulating. Bee-keepers who are interested in their bees and know how to handle them will not make this mistake. When the majority of the bees in the country were kept in straw skeps it was the usual practice to place them on stands, as near a wall or fence as possible. It did not then matter much, as they were not interfered with more than twice a year. This was in the spring, when the new swarms were placed in the skep; and autumn, when they were lifted, to be placed over the sulphur pit.

Happily this is now all altered. Old customs, however, die hard, as at the present time we know one bee-keeper of the old school who has about twenty stocks placed in a double row on a stand close to a wall. All manipulating has to be done from the front of the hives, and anyone who has had experience in a similar case will appreciate the difficulty of handling bees in such a position. Hives on legs about 18 inches in height are very convenient. But where hives are home made a stand composed of two 7-inch boards answers the purpose admirably. Stout posts should be driven into the ground about 4 feet apart. If some pieces are placed across each pair of posts, which should be kept level lengthways, but allowed to face 1 inch to the front, this will allow the moisture to drain off the alighting board. From the alighting board to the ground should not be more than 18 inches, and if a hive is placed over each pair of posts there will be ample room between them. There should be at least 3 feet of space at the back of the hives. The bees may then be manipulated with pleasure.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Exhibiting Plants (E. N.).—Many times have we requested that a completed schedule be sent with any inquiries on doubtful points of interpretation of any particular class. With nothing before us but the three lines sent, we can only say that no one knows whether you would be disqualified or not. If the literal interpretation of the class were followed you would be, but the judges may have authority for taking a broader view, and their decisions accepted as final. We cannot in the absence of a schedule containing rules and regulations give a more definite reply.

Liming Rose Beds (Kittie).—Soil that has got sour by constant manuring and very little digging would be greatly benefited by a dressing of lime. The lime is best air-slaked—that is, placed in a shed until it has fallen to a fine powder, due to the quicklime absorbing moisture from the atmosphere. Such is milder than water-slaked lime, though if inconvenient to wait for air-slaking, the freshly burned lime may be sprinkled with water, using no more than is necessary to cause the lumps to fall into an apparently dry flour-like condition, and when cool apply to the soil at the rate of half a hundredweight per rod. It is best to apply the lime, during fair weather, in the autumn, and leave it on the surface for a time before digging in, especially when water-slaked, in order that it may part with some of its causticity. Air-slaked lime, however, may be dug in at once. The next best time is in March, as the ground will then have become more or less dried, and in free working condition. For Rose beds that have been long manured we have found a mixture of best air-slaked chalk lime and fresh soot in equal parts by measure, mixed, and applied at the rate of half a pound per square yard as soon after the middle of February as the ground is in good working order, at once digging in with a fork, taking small spits, give excellent results in the growth and flowers of the Roses. The mixture need only be dug in 4 to 6 inches deep.

Raising Tomatoes (T. W. L.).—Tomato seeds may now be sown to raise plants for affording ripe fruit early in May. The seed should be sown thinly in well drained pots, pans, or shallow boxes, using light sandy soil, and placing on a brisk hotbed to germinate. Raise the seedlings well up to the light before they become in the least drawn, thinning so as to secure sturdy plants, and when well into rough leaf pot off singly into thumb (2½ inch) pots, sinking them to the seed leaves. Shade until the potting is recovered, then expose to all the light possible.

Amaryllises (J. V. C.).—Amaryllises should be potted firmly in rather sandy yet turfy loam, with a little crushed charcoal intermixed, in spring, about February if they can be placed in a genial temperature of 55° to 60°, and they start all the better if the pots are plunged in a bottom heat of about 80°. Care is needed against giving too much water at first, and before there is any growth to appropriate it. As the flower spikes grow and leaves form more water is requisite. After flowering a strong leaf growth should be encouraged in the full sun, never allowing any check through drought at their roots. About the middle of August the water supply must be reduced, and a dry atmosphere should be maintained, with free ventilation to assist the ripening process.

Winter Condition of Black Fly (Amateur).—The black aphid (*A. cerasi*) lives through the winter on the young growths of Cherry trees under favourable climatic conditions, or in glass houses, and sometimes in warm situations outdoors. These continue to increase parthenogenetically under such circumstances for a number of years. This process of reproduction by gemmation or budding is distinct from that by eggs. These eggs consist of the outer wall or vitelline membrane, which is practically weather-proof, the yolk or vitellus, the germ vesicle, and germ spot. All these parts are easily determined anatomically, but it is extremely difficult to refer the egg under examination to the species. The eggs (true) are produced by winged females at the end of the summer or in autumn, generally pale or yellow at first, but ultimately turning black.

Hampshire Soil (A Fellow of Botany).—1, The best manure to apply to garden soil, where the ground is full of flints and where chalk abounds, is half-rotted farmyard horse stable manure. The manure from cows is also excellent when not less than half-rotted. All kinds of vegetable crops thrive on chalky soils thus enriched, it being only a question of cultivation to make the soil grow anything that may be required by an establishment. We do not consider it would be wise to screen the flints, and it would suffice to remove such as interfere with the working of the land. It would be advisable to bring in as much fresh soil as you can, so as to deepen it. 2, Orchard trees that are full of moss and short of wood growths should be sprayed with a solution of caustic soda and potash, ½ lb. each to six gallons of water, choosing a dry day, when the weather is mild and the trees quite dormant. It is more effectual when used at a temperature of 130°, or dust the trees with quicklime whilst damp after fog or rain. If the trees require pruning, attend to this before spraying or liming them, a judicious thinning of the branches or twigs where crowded being of great benefit in cases of stunted growth. To the grass or land we should give a good dressing of manure, not less than 20 tons per acre, and the sooner the better. 3, The wall trees should be pruned if they are worth it; if not, uproot them and plant fresh ones, for trees destitute of health often take more "doctoring" than they are worth. If kept they will probably require manuring and dressing with an insecticide. If you cannot procure farmyard or stable manure apply some approved fertiliser, such as those advertised for fruit trees in our columns. 4, Peach trees have thriven with us on a soil full of flints and where chalk abounds, the silica being too insoluble to do them the least harm. What they suffer from is dryness, and that can be obviated by watering and mulching with manure in summer. 5, Peach and Vine borders of the very best are made from pastures of such land, using the top 2 or 3 inches with the turf. Such a medium is better than Surrey loam for Peach and Vine borders. 6, The best fuel for boiler furnaces is anthracite coal where the draught is good, but in some localities coke can be had readily, and then it may be the more economical. 7, Water obtained from wells on lime formations is injurious to peat-loving plants, and also prejudicial to fruits for syringing purposes, and should be treated with anti-calcaire before being used for such purpose. 8, Rhododendrons could be made to thrive by preparing beds for them of peat or other vegetable material, such as limeless turfy loam mixed with half leaf mould, and mulching with cow manure. 9, Herbaceous plants of nearly every kind succeed on such soil as you describe if the borders are properly made, adding pure soil and some manure where the material staple is shallow and loose. 10, The hardier Tea-scented Roses and the Hybrid Perpetuals would unquestionably thrive under proper treatment and due preparation of the beds. The question of hardiness would be influenced by the altitude and exposure as regards the Teas, though they would succeed with protection in severe weather. 11, The soil is suitable for Figs, but whether they would succeed as standards depends upon the situation; they only answer as such in favoured positions. If you mean growing them against walls, if these are high enough there is no doubt of their succeeding on a south aspect if the trees are properly managed. You may rely on the information we give. Success is a question of intelligent routine.

Fresh Blood Mixed with Turfy Loam and Farmyard Manure for Top-dressing Vine Border (M. R. D.).—Blood is an excellent manure for Vines, but you would have done better by mixing with it an equal quantity by measure of wood ashes before adding to the twelve barrowloads of turfy loam and three barrowfuls of farmyard manure, then mixing the whole together. As you have not done this, and may not be able to procure the wood ashes, add to the compost the same amount of air-slaked lime, sprinkling it all over the heap, and turning at least once so as to incorporate all well together. After placing the compost on the border, it would be well to sprinkle on each square yard a handful of a mixture of three parts steamed bone-meal, two parts muriate of potash, and one part sulphate of magnesia, leaving on the surface for the water given in watering to wash in. We do not approve of raw blood being applied to Vine borders. It ought to have been composted at least three months before use; but with the treatment advised you may use it after mixing.

Dressing Vines with Caustic Soda and Commercial Potash Wash (R. A. C.).—The article may be procured of or through a chemist or horticultural sundriesman. The caustic soda (98 per cent. purity) and commercial potash or carbonate of potash, commonly called pearlash, should be used in equal proportions, say 1 oz. each to 1½ gallon water, dissolving in hot water and applying with a half-worn, clean, painter's sash brush at a temperature of about 130°, reaching well into the holes and crevices, but not using lavishly. It should be applied whilst the Vines are quite dormant. For the Figs it must be more highly diluted or to two gallons, as it sometimes injures the young wood, and for them it is better to use soluble petroleum, applying according to the instructions, as there are various strengths of the article. The other articles you mention are not insecticides for applying to the stems of Vines or trees, but valuable fertilisers for applying to the soil. If you fail in procuring the caustic materials send us a stamped directed envelope repeating your request.

Sulphuring Vinery (F. C. C.).—The practice of burning sulphur in vineries when the Vines are at rest is practised by some growers of Grapes for marketing, but, so far as we have observed, with little, if any, effect, for the Vines were infested with red spider the following summer. This pest harbours in various parts of the house—the wood-work, walls, and borders, cracks and crevices, and the sulphurous fumes fail to reach all the hibernating pests, and at any rate they wake up lively enough when the time for action comes. Thorough cleanliness is the best preventive, the woodwork being thoroughly brushed and washed with carbolic soap water; the glass cleansed inside and outside with clear water; the walls limewashed, and the loose surface soil of the border removed, and a top-dressing given of good turfy loam with a fourth of well decayed manure added; also sprinkling on each square yard a good handful—about 4 ozs.—of a mixture of three parts dissolved bones, two parts sulphate of potash, and one part sulphate of magnesia, well mixed. The top-dressing should not exceed 2 inches in thickness. Red spider also hibernates on the Vines, beneath the loose bark, and in the holes and crevices of the roots; hence we advise their being dressed with a solution of caustic soda (98 per cent. purity) and commercial potash or pearlash, 1 oz. each to 1½ gallon of water, applying with a brush at a temperature of 130° to 140°. This will kill the eggs as well as the larvæ and adults of most pests infesting vegetation. We do not advise the sulphuring, though if you like to try it a good handful of sulphur would be sufficient for the size of house you name.

Planting Vine against an Outside Wall (Amateur).—You may take up, plant, and prune the Vine at once, preserving as many roots as possible, not letting them get dry during the process of removal. Dig out a deep trench as far from the stem as you can, going quite below the roots; then fork away the soil from the roots into the trench, throwing it back with a shovel as the work proceeds, and in this way the roots will be kept clear of the soil, and the greatest number secured. If the soil in your garden grows fruit trees well, a Vine will grow in it also; but you cannot err by placing in a foot in depth of turfy loam for the roots to be spread on, and covering them with some of the same kind 4 or 5 inches deep. They must be spread out quite straight, cutting off all broken ends and bruised portions, working the soil well round them and pressing it down moderately firm, but not treading it hard. When finished the surface may be 4 or 5 inches above the level of the surrounding ground. A layer of longish manure spread on to exclude frost will complete the work of planting. The pruning should be severe, cutting off all the side or lateral growths—that is, those made during the present year, leaving only about two eyes or buds of each next to the main rods; or, if preferred, the main rods may be cut down to any desired extent, and young growths retained towards the base for training, if in this way, the wall space would be more effectively occupied. The main branches on Vines on walls should be 3 feet apart, so as to afford space for securing the fruit-bearing laterals between them, taking off their points so as to leave one leaf beyond the bunches. These side growths should be 18 inches apart, more rather than less, selecting the best as soon as bunches are visible, and pulling off the others gradually, allowing none to remain after those desired are secured to the wall. If the thinning is completed at once some of those intended to be retained may be broken in bending them to the wall, hence the wisdom of having a few in reserve. Lead-coloured paint should be well rubbed into the wounds after pruning.

Evergreens and Deciduous Shrubs for a Town Churchyard (T. S.).—Box, Yew, and Aucuba japonica are the best evergreens to stand the smoke of towns; Lilacs, Snowberry plants, Laburnums, Gueldres Roses, and common Honeysuckle the best flowering deciduous shrubs. If the ground is hard it ought to be trenched two spits deep, as the plants ought to be planted before the first half of March is out. The place should be kept as clean from weeds, and as regularly attended to, as a gentleman's garden, till the plants are big enough to almost meet.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. The practice of pinning numbers to the eyes of the fruits tends to destroy one of the most characteristic features and increases the difficulty of identification. When Plums are sent to be named young wood of the trees should accompany them. Leaves of the trees are necessary with Peaches and Nectarines, with information as to whether the flowers are large or small. (W. B.).—Early Red Calville. (C. N.).—1, Wyken Pippin; 2, Court Pendu Plat; 3, Dutch Mignonne; 4, D'Arcy Spice. (E. T.).—1, Wellington (Normanton Wonder); 2, Ribston Pippin; 3, Beauty of Hants; 4, Newton Wonder; 5, Roundway Magnum Bonum; 6, Warner's King. (C. B.).—1, Bramley's Seedling; 2, Dr. Harvey; 3, Blenheim Pippin; 4, Cox's Orange Pippin.

Names of Plants.—We only undertake to name species of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (X. Y. Z.).—1, Lnculia gratissima; 2, Justicia carnea; 3, Paper White Narcissus. (L. R.).—1, Pteris longifolia; 2, Woodwardia radicans; 3, Davallia canariensis; 4, Asplenium viviparum; 5, Adiantum cuneatum grandiceps; 6, Asparagus plumosus nanus; the latter is not a Fern as you suppose. (Evergreen).—1, Taxus baccata; 2, Ligustrum ovalifolium (the Oval leaved Privet); 3, Thuiopsis dolabrata; 4, Cupressus Lawsoniana, seedling form; 5, Thuia Lobbi; 6, Retinospora ericoides. (F. O.).—Crotons come within the category of florists' flowers and can only be named by comparison in a large collection.

A BOON TO MARSHLAND.

MOST educated people have a fair workable knowledge of geography—or at any rate they think they have—but it really is wonderful how often we can be caught tripping. We do not learn everything at school, and there are many parts of dear old England (divisions we might say) the names of which are totally unknown to us. We remember years ago how a batch of boys and girls were "floored" at the examination of the Cambridge Local by the request to place Ludlow and point out the Doldrums.

We fancy we know all the shires of England by heart, but have many south country people heard of Hallamshire and Howdenshire with Marshland and the Isle of Axholme? We believe Sheffield is the capital of Hallamshire, and in days gone by there was a horse fair held in Howden, second only to Lincoln. Howden was in the heart of a really good coach-horse breeding district, and you would see there the élite of London buyers. Howden is not what it was; the demand for coach horses of the old type does not exist, and although at Howden you may find many a real good Irish hunter, and may be English ones too, Howden may write Ichabod above its gates. Where is Howden? Sail up the Humber, noting with interest the rich tracts of land on either side, pass the point where the Trent pours its large volume of water into the estuary, and finding yourself in the Ouse travel up as far as Howden Dyke or Booth Ferry. Then you have the port of Goole on one side and Howden on the northern bank. In old days the traffic across Howden Dyke and Booth Ferry was enormous. You may see at Booth Ferry still a gigantic old house, once the inn, with its ranges of stabling and ample accommodation for man and beast. Now it is turned into a farm house. No need for the hostelry now. The N.E. Railway has done away with the coaches, and the big weekly markets have superseded the fairs. Goole is comparatively a modern port; we have watched it grow, and its vigour is such that we can put no limit on its capabilities. It is the centre of a purely agricultural district situate on a wonderful waterway; in leed,

what the farmers and inhabitants would do without that waterway one cannot imagine.

Marshland is a low-lying district not attractive to the eye of the lover of the picturesque. We are wrong perhaps. The rivers have charms of their own, and the high banks with the path atop is at least novel and interesting. We have seen some wonderful set effects there; but, better still, we have seen some marvellous crops. The land has all been subjected to that peculiar kind of tilling known as warping—i.e., the rich, muddy river is allowed to overflow certain fields, and leaves on them much alluvial deposit. The result is astonishing.

There are many things that must be seen to be believed. No Marshland dweller could grasp the idea of the beauties of forest scenery. No stranger could fathom the loneliness and isolation of a dwelling on Exmoor or Dartmoor. Some of the high wolds of Yorkshire and Lincolnshire bid fair to equal the moors in point of solitude. No one unless he has ridden after hounds knows the depth of a Holderness drain nor the strength of a Leicestershire ox fence, and no pen of ours can describe the mud of Marshland.

Reclaimed as it has been bit by bit, carefully drained, carefully banked, it needs something less than a shower to make the roads well nigh impassable. At the side of every road you will notice a line of single flag stones. Without that permanent pathway pedestrians could not stir a step. This flagged causeway was originally intended for strings of pack horses, which have vanished, as many other things have done. Here are several villages quite ten miles from a station, and a ten miles of appalling road. When it is considered that every ton of Potatoes—and many a thousand pounds' worth are grown there—every quarter of Wheat, and every ounce of tillage has to be laboriously drawn in heavy waggons by horses the whole ten miles, the work and labour and wear and tear must be something awful. A man with a pair of horses can only deliver one load a day, and then has well earned his wages.

Some of the bye lanes are simply quagmires, down which it is all six horses can do to draw a load of Potatoes. The expense of making these bye roads decent would be incredible. There is no foundation whatever, and any stones put on would only share the fate of those thrown into Bunyan's Slough of Despond; they would simply disappear and leave no trace. We cannot say a great deal in favour of the main roads, although the rates are tremendously high and qualified men are employed freely. As in manufacturing towns they say you cannot make money without making muck, so you cannot have rich alluvial soil in conjunction with good highways. This is as it used to be up to this year of grace, and now a wondrous change has come over the face of Marshland.

This autumn has seen the inauguration of a light railway, and the boon it is conferring on the agriculturists is simply unspeakable. It has been wisely planned, and taps the most congested district. It will simply revolutionise the working time table. We wonder what the horses would say if they could speak; we know what the men say. No more long hard days to Goole or Keadby stations; days when there is so little to show for wear and tear to man and beast; days that are apt to take off all the gilt from the farmer's gingerbread. This is one of the best districts where the experiment could be made. We are speaking just of the beginning of the scheme. The Isle of Axholme is to have a line, and other outlying townships of Marshland, such as Garthorpe and Luddington, are to be touched by another branch.

Whether this opening out of Marshland will have any effect on the Flax-growing industry we are hardly in a position to say. There used to be a time, when we were in our youth, that we saw field after field of the bright blue flower. One would almost think that, with plant erected at Goole, this industry might be worked again on a co-operative scheme; but there are wise men in Marshland, and enterprising men, so if there is anything in it they will soon know.

There are two other isolated districts where a similar scheme of light railways is about to be tried. There are some isolated villages in North Holderness which have suffered long from their isolation.

We once had the privilege of conveying all the produce of a 600-acre farm ten miles to the nearest station, and carting back every atom of artificial manure and cake. Now that required some horse power.

There is another district in South Yorks and North Notts, just on the confines of a teeming population, and yet without any means of transport but carts and horses; a market in view, but difficult of access. The railway is only a question of time. Let us hope the promoters will make all possible speed in getting the thing into working order.

WORK ON THE FARM.

We are once again commencing the work of the new year and trust that it may be got through in a satisfactory manner. Work on arable farms generally is likely to be much less formidable in itself during the next four years, as the series of good fallowing seasons we have just passed through should have left no legacy of twitch behind them. It is a good thing that work is likely to be light, for the labour difficulty is more severe than ever.

The calling out of the reserves, militia and volunteers, has strained to an extreme an already tight labour market. An ironmaster told us a week ago that he wanted 100 more men and could not get any. A state of affairs like this is sure to further drain the resources of the villages.

We have had frost, then a decided thaw with heavy rain, and now a sharp frost again, with no snow protection for the roots, which are likely to suffer, as they never looked like standing much frost, for though small they have grown very much out of the ground.

Ploughing is well forward, so that a stoppage will be of little account, and muck leading will soon be finished. Many farmers are again threshing freely, in some cases perhaps in order to find employment for the hands, in others to get the work done whilst the horses are unemployed and the ploughmen can be made use of in the stack-yard, for extra hands can hardly be obtained. It is a long time since the casual labourer has had such regular employment.

The grain markets, unlike those of fat cattle, have been very dull, and are likely to be so, for no doubt the high bank rate has caused a certain amount of unloading of stocks in warehouse, so those who can keep their holdings until summer may reap much advantage. Of course new political developments might cause an earlier reaction.

EXPORTATION OF STOCK.—The exportation of live stock for breeding and other purposes from this country goes steadily on at all times. During the present year such stock amounted to the value of £828,422. This, we learn, includes horses, many of which are exported not for breeding but working purposes, as well as racing. Their total value amounted to £622,110.

ROOTS FOR PIGS.—In some Danish experiments to determine the value of Turnips and Mangold Wurtzels as feed for hogs, it was shown that these roots may be fed as a part of a pig's ration with satisfactory results. The feeding value of roots was shown to correspond, says a contemporary, very nearly with their dry matter content. Roots rich in sugar produced better results than those light in sugar. The increase in live weight, however, followed more closely the dry matter content than the sugar of the roots. The hogs were fed a ration which contained three-fourths grain and one-fourth roots. In addition, the pigs received buttermilk, skim milk, and whey, either alone or mixed.

OLD TIMES.—There are many grey-headed farmers who remember the good old days of single ploughs, land planting, grain cradles, and threshing floors and flails, when it was necessary to get out of bed before daybreak, feed the cows and teams so as to be at work by the time it was light enough to see; to work until the dinner horn sounded, feed and water the team, eat dinner and return to the field and work until dark, after which feeding, and chopping wood occupied the time until nine o'clock, when all hands would hurry to bed, hurry to sleep, and be ready for the early crowing of the cock, and to repeat the programme six days in every week, unless it rained, in which case the time was spent over some labour that could be performed under cover. Farmers in those days were, or seemed to be, contented and happy, simply because they had enough to live on and no debts to pay. Now, we can do our ploughing while riding on a spring seat, and under an umbrella if we so desire; plant 10 acres a day instead of two; have all our grain cut in a day, and threshed during the forenoon. All our work may be done with time-saving and labour-saving machines, but we cannot help grumbling more than our fathers did when working from twelve to fourteen hours a day. Labour-saving inventions and improved processes are of little use unless they really save labour. Labour was inflicted on man as a curse, and in the present and past conditions of society became a necessity. But, like convicts in prison, our punishment is being relaxed on account of good behaviour, though we may never regain the lost liberty to live without labour. Let us make the most of our opportunities by spending the difference between the old hours of labour and the new in self-improvement and wholesome recreation, otherwise we are none the better for modern improvements.—("Rural World.")

BARR'S SEED GUIDE NOW READY (FREE).

BARR'S SEEDS

OF FINEST SELECTED STRAINS AND TESTED GROWTH

THE BEST SEEDS IN THE WORLD for securing a supply of Vegetables "the year round," and for keeping the Flower Garden always gay; and with abundance of Flowers to cut for vases and bouquets; also Seeds of Plants for Greenhouse decoration summer and winter.

BARR'S SEED GUIDE contains a select List of the best Vegetables and the most beautiful Flowers for Garden and Greenhouse. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors, SENT FREE ON APPLICATION.

BARR'S 21/- COLLECTION OF VEGETABLE SEEDS contains a liberal assortment of the following useful Vegetables: Beans (Broad and French Beans), Beet, Borecole, Broccoli, Brussels Sprouts, Cabbage, Capsicum, Carrot, Cauliflower, Celery, Colewort, Corn Salad, Cucumber, Cress, Endive, Herbs, Leek, Lettuce, Melon, Mustard, Onions, Parsley, Parsnips, Peas, Radish, Salsify, Savoy Cabbage, Scorzoneria, Spinach, Tomato, Turnip, and Vegetable Marrow.

OTHER COLLECTIONS of BARR'S VEGETABLE SEEDS, 5/6, 7/6, 12/6, 42/-, 63/-, and 105/-.

These Collections sent carriage paid on receipt of remittance. Full particulars on application.

BARR'S CHOICE FLOWER SEEDS.—The "Seed Guide" contains a Select List of all the most beautiful Annuals and Perennials. Special Collections for all purposes, and many Sterling Novelties.

All Seeds sent Carriage Paid on receipt of remittance.

ECKFORD'S SPECIALITIES

ONLY GENUINE DIRECT FROM WEM

AWARDED 46 GOLD & SILVER MEDALS

SWEET PEAS!

The BIGGEST SUCCESS of all is **ECKFORD'S GIANT SWEET PEAS**. The PURITY and STAMINA of these Home Grown Stocks are so conserved by SPECIAL METHODS of CULTURE that the seeds are PHENOMENAL for UNRIVALLED STRENGTH and VITALITY, and with proper cultivation, give the HIGHEST POSSIBLE MAXIMA of results! Prizes offered in 1900 alone exceed £40!

Collections from 1/6 upwards.

(See particulars in Catalogue.)

See beautiful plate of SWEET PEA NOVELTIES for 1900, sent gratis with each Catalogue.

CULINARY PEAS!

ECKFORD'S CULINARY PEAS are positively UNRIVALLED by any on the Market for FLAVOUR and CROPPING CAPACITY! ENORMOUS YIELDS under favourable conditions. Collections for 5 months continuous supply (See page 2 Catalogue.)

PURE VEGETABLE SEEDS!

Results from ALL QUARTERS prove that **ECKFORD'S SEED**, for PURITY, VIGOUR, and YIELD, are the CHEAPEST and BEST ever offered to the Public! Collection for 12 months supply, 12/6, 21/-, 42/-, 63/-, 105/-, all carriage paid. Other Collections, 2/9, 5/-, 7/6, post free.

PALMS IN WINTER.

THE culture of the many species and varieties of these indispensable plants is a decidedly interesting branch of horticulture, for although we do not see such quick returns in the shape of growth as with many other plants and crops, yet all true cultivators delight to watch the gradual development of clean healthy fronds as the plants respond to good treatment. The depth of winter is a pleasant time to those who spend the greater part of their working hours in Palm houses, for there the temperature is warm and enjoyable, in marked contrast to the biting cold without. I often look back with pleasure to the autumn and winter months which I once spent in the Palm houses of a great metropolitan nursery, and the memory has just brought to my mind the idea that a few notes on Palm management might prove useful to Journal readers at the present time.

The regulation of heat and moisture is a matter of importance in Palm growing, and when a house is devoted entirely to such plants it is easy matter for an intelligent and attentive man to maintain ideal conditions. In private establishments gardeners often have to grow their large specimens among miscellaneous collections of plants, and under such conditions I often wonder that they are kept in as good health as they are, although they may lack that pleasing "gloss," which expert Palm growers know how to secure.

Unlike so many other plants, Palms do not seem to be dependent on sunshine to make satisfactory progress. Of course during bright weather they, as a rule, grow more quickly than when the days are dull and dark, but with sufficient heat and moisture round them they may always be depended upon to grow steadily throughout the winter, hence the reason that in many commercial establishments the whole stock of Palms is thoroughly overhauled, and receives extra attention during the dull season. For growing plants in pots, ranging from 3 to 7 inches, the type of house I prefer is a rather wide span-roofed one with a central stage, and side stages not more than 3 feet in width. If all stages are covered with spar or pounded clinkers, and

hot-water pipes fixed beneath the central as well as the side stages, the heat is evenly distributed throughout the house, and with proper attention to damping and syringing, Palms in such houses may be kept in superb health.

It is not wise to be too particular in regard to temperatures; the great aim should be to always have the pipes comfortably warm, and to avoid sudden changes of temperature. If the thermometer ranges from 60° to 70° at night, and a few degrees higher during the daytime in dull weather, satisfactory progress will be made. During cold windy weather the thermometer may be allowed to fall several degrees lower as long as the pipes are thoroughly warm. In early morning the first duty of the attendant in charge of a Palm house is to damp the walls at the back of the hot-water pipes, and the floor or space beneath them. This to be done only when the temperature is at its proper point, on any occasion when it is somewhat low the damping ought to be deferred for a time. During the morning after the watering has been performed, and the temperature has risen, all dry places in the house should be moistened, including the space on the stages. Thoroughly healthy atmospherical conditions are then secured. During the afternoon the walls near the hot-water pipes usually need damping again, even in foggy weather, and the plants are then comfortable till the next day.

The plants require little syringing in the depth of winter, and should only receive it when bright gleams of sunshine occur, except in the case of plants in an extra dry corner, such as one generally finds in nearly all houses; in these cases, when hard firing is resorted to, it may be necessary to syringe the plants daily for a time. An expert with a good jet syringe performs the work in such a way that every particle of the under as well as the upper sides of the fronds is thoroughly moistened without using enough water to sodden the soil in the pots. The heavy-handed syringer cannot be tolerated in winter time. As the days lengthen and become brighter daily syringings will be needed. At the risk of being considered precise and prosy, I have treated this matter in detail, because I know that it is one of the most important points connected with successful Palm growing.

In regard to watering little need be said, as the same care is essential when dealing with newly potted Palms as with other plants, and when the soil is packed with roots far more liberal quantities are required. Whenever watering is done do it thoroughly, then withhold it till the soil is fairly dry again. Immense quantities of Palms are now raised from seeds, both in this country and on the continent, and during the winter months large numbers are potted. In all stages small shifts should be given. Young plants in "thimbles" when well rooted ought to be potted in 3½-inch pots, and in subsequent stages transferred to 5-inch, then to 7-inch ones, in which sizes they are in great demand for decorative purposes. Many young plants in the early stages are grown entirely in leaf soil, but large specimens do not keep in good condition long when potted in such light material. A compost which may be relied upon, is one formed of two parts of fibrous loam—inclined to be heavy rather than light—one of peat, and a tenth of sand. This compost should be pressed very firmly with a potting stick, and the surface finished with the fingers, always remembering to leave sufficient space for holding water enough to moisten the whole ball. If the soil about the root is moist when potting is performed, water will not be required for some days, then it should be given through a rose, and in the same way for some time after.

The most troublesome insects Palm growers have to contend with are the small white and brown scales, and although many insecticides are supposed to kill such pests without injury to the plants, few, if any of them, will really do so except when used at too great a strength to be safe. If the plants are dipped in an insecticide as soon as the slightest trace of scale is noticed, it may often be destroyed, but when once these pests gain a thorough footing the only effectual way of clearing them is by the tedious process of sponging; then by periodical dippings the enemy may eventually be overcome. The greatest care should, however, be exercised in purchasing only such

plants as are quite clean, for even if the price is high they are cheaper in the end.

Kentias are undoubtedly more largely grown than any other species of Palm, and either for private or commercial establishments they stand unrivalled for decorative work. Belmoreana and Fosteriana are the best varieties; the former is usually preferred to the latter on account of its more elegant fronds. Cocos Weddelliana still maintains its position as the best among the small graceful formed section, but Geonoma gracilis is well worth growing. Areca lutescens is a beautiful Palm, but unfortunately does not last well in rooms. A. Baueri and A. sapida are noble as large plants for conservatories, as they produce such bold leaves. Cocos plumosa is a gem among species which grow tall and slender, without undue spread of frond. If we add to the above list Latania borbonica, Corypha Wagoni, Phoenix canariensis, P. rupicola, Raphis flabelliformis, and Seaforthia elegans, I think for decorative purposes we could not well improve upon it. Other choice and rare species there are, of course, but such come only within the reach of a few.—PLANTSMAN.

LATE SPRING PLANTING.

WHEN I read the remarks by "H. R. R." (on page 571) under the above heading, I said to myself, surely there is such a thing as riding a hobby to death; and how this poor animal has been kept going up to the present by dint of whip and spur I know not. Certainly, to read the bulk of the articles on planting fruit and other deciduous trees which one comes across in the columns of the horticultural press, one would arrive at the conclusion that the proper time for this operation does not extend beyond a fortnight, or at the most a month, in the autumn, and that to attempt to plant at any other time is, as your correspondent calls it, a makeshift.

Unfortunately for nurserymen no one, so far as I can see, attempts to confute these statements about early planting, and consequently the amateur works him or herself up to a pitch of frenzy, and writes to the nurseryman about the second week in November, saying that it is too late to plant fruit trees, and that the order which has been given must be countermanded; upon which the nurseryman smiles a sickly smile, and after using his blue pencil to cancel the order, dictates a letter, as soothing as he can make it, to his customer, explaining that, with the best of endeavours, it is out of the question, that all one's customers can be supplied in one week, and so on and so on.

But what are the facts of the case? I believe, with your correspondent, that there is a time in the early autumn, when the leaves have changed but are still on the trees, when, given sufficient moisture in the soil, deciduous stock may be transplanted with every certainty of success, and when they will make fresh roots so quickly as to be established in their new quarters before winter sets in. For many years past we have supplied fruit trees to local allotment holders and market growers during the early part of October, frequently during the "Goose Fair" week, which is the first week in the month; the trees have been lifted in full leaf, and we have sometimes thought that they must suffer in consequence; but not at all; they are taken by cart the moment they are lifted and planted again as promptly as possible, and we have never heard of one of them dying.

Every practical gardener has had the same experience in removing trees early in the season from one part of a garden to another, and most, or many of them, have written to the horticultural press upon the subject. But, my good friends, of what use is the information to the general public? Not every gardener would care to drive to the nearest nursery, have his trees lifted, and see that they were replanted the same day, either by daylight or candlelight; whilst to the ordinary planter, who is tolerably happy if his trees get planted the same week that they are lifted, the information is of no use whatever; for if the trees lifted thus early are not replanted at once their bark shrivels, and they suffer considerably, even if they do not die. We must admit, then, that this very early planting is out of the

question for those whose trees have to travel long distances by rail, for to despatch trees safely by rail one must wait until the bulk of the leaves are fallen.

I also agree with your correspondent that there is a time for planting late in the spring, when trees are on the point of bursting into leaf, and even when the leaves are partly unfolded, when, provided the soil is in good condition and the trees are lifted and replanted immediately, they seem to suffer no check. But this, again, is of no use to the ordinary planter who has to procure his trees from a distance, for with a long journey the roots would be dried and the leaves shrivelled.

Where I join issue with your correspondent is in considering that all the time between these two extreme points of the planting season is an unsuitable period for planting. Every gardener, nurseryman, or market grower knows from long practical experience that fruit trees may be planted with safety at any time between November and March, and that if one can lift and replant at once the season may be extended both ways if the weather be favourable. But the point which I think it is most needful to impress upon the inexperienced is, that, no matter what the month is, the great factor to insure successful planting is that the land shall be in good condition at the time the trees are placed in their final positions.

It will not need much explanation to show that upon strong, sticky soils, in districts where the average rainfall is at all heavy, this must mean early planting, for when the winter's rains have fallen these soils are, as a rule, difficult to plant satisfactorily. Again, we all know that certain stock, such as Roses, Briars, and a few other things, succeed best when planted early; yet even here the exigencies of business or stress of weather often upset the routine of a nurseryman's work, and I find, on referring to my diary, that in 1892 we were planting standard Briars March 21st which should have been in before Christmas, and that the result was a good growth. Setting aside exceptional soils and subjects, I maintain that trees planted when the land is in good condition succeed equally well if planted in November, December, January, or February.

Experiments upon this point have been undertaken at the Duke of Bedford's Experimental Fruit Farm, the results of which we shall look forward to seeing in print; but so far as they have gone, I think they bear out my statement that the date during the months named has much less to do with successful planting than has the condition of the soil. I always hold that trees cannot be satisfactorily planted in mud, and therefore if trees arrive when the ground is in a bad state, either through too much wet or the break up of a frost, they should be laid in a trench, with the roots well buried, until the land is in a fit state for planting, be that in a week or a month; indeed, when any considerable number of trees have to be dealt with they should always be laid in a trench prior to planting, as nothing is more injurious to trees than to have their roots exposed for hours, or even days, to the influence of drying winds or sun.

One other point about planting is that the trees should be looked after when the planting is finished. In these days, when so much has been written about careful planting, it is rare that one hears of really bad work, such as a correspondent related to me a while ago. He said to me, "My neighbour, Mr. So-and-so, has had some trees from you; and if they die, you ask him how they were planted. I saw the work done, and it was in this manner: The holes excavated were about the size of a good silk hat, and the trees were twisted round to get the roots in, and then some soil was thrown on the top, and a stamp of the heel given to complete the operation." This, although told as related to me, is, I venture to think, an extreme picture, yet trees must be badly planted or shockingly neglected afterwards to account for so many dying.

As a rule the man whose trees die is the man who purchases a dozen, out of which half die; the man who buys 500 sometimes loses two or three. Now I venture to guess that the dozen trees were days out of the ground before being planted—I have known them to lie in a back yard a week—whilst the 500 would be put in the ground as fast as men could lay them in. But even when planted the work is not over, and trees which are removed late in the spring should have the ground around them constantly stirred with the hoe to fill up all cracks and prevent evaporation from the soil.

During the last few years we have transplanted annually some 2000 to 4000 fruit trees, and this at a time when all sales have ceased, owing to the season being so far advanced. In 1897 we did not finish till April 15th, and the men planting the trees said they would all die; nevertheless by constantly stirring the ground with the hoe, watering being quite out of the question, our losses have not averaged more than two trees in 1000, whilst the trees thus removed have carried crops of fruit fit for an exhibition table. Some trained trees transplanted April 15th, 1897, have this year (a dry season) shoots from 6 to 7 feet in length, and trained Apricots removed late in March this year have shoots $1\frac{1}{2}$ to 2 feet high. All this I attribute to careful planting, and to the use of the hoe on the surface of the soil, and I am sure that if more attention were paid to this form of cultiva-

tion we should not see so many stunted looking trees about our gardens and plantations.

In conclusion let me add that I hope your correspondent "H. R. R." will not say that my examples are all culled from late planting. I notice these as cases where difficulties were overcome. The so called dead time of January and February is, when the bulk of a nurseryman's work is of necessity obliged to be done, and I think that the results will, as a rule, bear comparison with any planting done at what is generally considered a more favourable time, the exceptions being where land was planted when too wet; when this has been done the result can generally be seen for more than one season. These remarks are intended to apply chiefly to fruit trees; where evergreens and Conifers have to be taken into consideration I should not advise planting during the early months of the year.—A. H. PEARSON, *Chilwell Nurseries, Notts.*

GLOXINIAS.

THE Gloxinia occupies a prominent position among stove tuberous-rooted flowering plants. With a good collection of tubers flowers may be produced from April to October. Large tubers make a considerable amount of growth, and when in bloom are very attractive. Medium sized tubers form neat and effective plants for general decoration in an intermediate house. During summer greenhouse treatment suits Gloxinias, though small tubers and seedlings grow better in a moister atmosphere.

In commencing the culture of Gloxinias, perhaps the most interesting method is to raise tubers from seeds. A temperature of 65° is requisite for this. In a well heated stove this heat can usually be maintained in February, which is a good time to sow seed. It may be sown in January in bottom heat not below 65°, only care must be exercised that the seedlings receive no check. The compost employed should consist of sandy peat, leaf soil, and sand, well intermixed and used moist. Place this in well drained pots or shallow seed pans. Make smooth and level on the surface, and give a gentle watering. When the water has drained away scatter the seed thinly on the surface, and follow with a slight dusting of sand—fine white sand. To lessen the need for water, which ought not to be required until the seed has germinated, cover the pan or pot with glass, and darken with moss or paper. If not sown too thickly the seedlings will grow sturdily from the first.

When the plantlets are of sufficient size to be lifted with a label they may be removed from the seed pan, transferring to a similarly prepared pan, placing them an inch apart where they will be able to strengthen prior to potting them singly in small pots. Heat, moisture, and subdued light, with the pots standing on a moist base, are essential matters in encouraging growth. Under these conditions great advances in growth will be made, and before the summer is over, or at least in autumn, these early raised seedlings will commence to flower. They cannot flower so profusely as larger tubers, but even if only a few blooms are produced it serves to show the character of the plant and the colour and quality of the bloom. In autumn the tubers may gradually go to rest, assisting them to do so by affording less and less water until they lose their foliage. Place the pots on their sides for the winter in a cool, dry part of the house.

The culture the second year commences when the tubers start into growth. They will do this naturally in the pots they are dried off in, but they must not be allowed to do so for long before shaking away the old soil and repotting.

The compost for potting tubers should be rich and generous. Peat and loam of a fibrous character may be broken up in equal quantities, adding half of leaf soil and half decayed manure with sand and charcoal. Place the tubers just below the surface, not burying the new young growth. At first the pots should be small, eventually shifting the plants into larger pots when the first are filled with roots, and in this size the plants may flower. Water must be given sparingly at first, heat and moisture being the chief aids to growth, but as this advances increased water will be demanded by the roots.

Though Gloxinias enjoy in the early stages artificial heat and moisture, there is no need to continue it all through the season, as when the plants come into flower greenhouse treatment is adapted for them. The very earliest started tubers will, however, require the continued temperature of the stove or intermediate house if they bloom before June.

Only a first-class strain of seed should be dealt with. The spotted varieties have large and varied flowers with delicate markings, scarlet and blue usually are the predominating colours. If many white-flowered Gloxinias are required a packet of seed of a white strain should be sown in preference to depending or obtaining them from a mixed stock. As a rule the erect-flowering varieties are kept separate from the drooping-flowered varieties. Both are worthy of culture, though some may prefer the erect-flowered varieties as being the most useful and showy for general purposes.—E. D. S.

SHOW SCHEDULES.

"W. G." (page 561) cannot have seen many autumn exhibitions during the last few years, or he would not suggest the inclusion of a class for "miscellaneous plants arranged for effect." Nowadays the exception is to find a show without such a class. Truly, as he says, the Hull Society does include this in their programme, and in no other exhibition are such groups to be seen. I do not attach much importance to the suggestion to include more formally trained specimens. These are gradually being left out, especially the standards and pyramids. Beyond examples of cultural skill, what artistic effect or even use can be claimed for such, I would ask?

To make our autumn exhibitions more pleasing new departures are required. In plants the freely flowered examples of single Chrysanthemums, Pompons, and the smaller forms of Japanese, intermixed with Palms and other suitable foliage plants; and dwarf plants suitable for conservatory decoration carrying exhibition blooms in small pots, showing the value of the Chrysanthemum in that form, would be a pleasing addition to our shows. The height of growth ought to be stipulated, as also should the size of the pot. Both of these are practical suggestions, and would produce desirable results.

In cut blooms any form of arrangement that dispenses with the orthodox cup, tube, and stand would be welcome; or perhaps not dispense with this plan entirely, but add other methods for comparison, and allow the best to preponderate in the future.

Chrysanthemums, large and small, are admirably adapted for disposal in vases of almost any type, with or without added foliage. There is therefore abundant scope for committees to give the public more variety at their autumn shows. Let us see if they will rise to the occasion.

DECORATIVE VARIETIES.

As "W. S." (page 561) correctly states, decorative varieties are equally as valuable to many growers as the popular show blooms are to exhibitors. The latter, too, pay special attention to the decorative aspect; in fact, they are generally the men who ascertain the qualities of the newer varieties for both purposes. Many sorts which are unsuitable for exhibition are most valuable additions to the decorative section.

For the information of "W. S." and others I have noted a few deserving varieties that, added to those named by him, will provide bloom in quantity, and extend over a long time. R. Hooper Pearson is without doubt the finest yellow flowered Chrysanthemum for this purpose. The lustre of colour is rivalled by none; while the habit of growth is all that is required. Mr. Jones has given the Chrysanthemum world many sterling novelties, but none better than this. Clinton Chalfont is a cross apparently between a Japanese and a reflexed variety. The florets are broad and stiff, forming just the flower required for vase work; the colour is rich. The new Chevenx d'Or, one of the "feathery" type, is paler in tint, but very effective in a mass. Madame Liger Ligerneau is dwarf in growth, clear yellow in colour. Hugh Crawford, too, is a useful addition to the Japanese section. J. E. Clayton, a yellow sport from Eva Knowles, possesses all the characteristics of a decorative Chrysanthemum. Golden Gate is one of the best of late yellows, its broad florets having a tawny tinge about them that affords variety.

Bright colours are extremely useful in this section, especially when they flower later than ordinary sorts. H. J. Jones easily heads the list in this colour. The blooms are exceedingly bright, the growth stiff and floriferous. Reginald Godfrey is dwarf and stiff in habit, just the type for vase work; the blooms are full and solid. Joseph Chamberlain gives a colour equalled by no other, while Matthew Hodgson and Royal Standard are also desirable varieties. Rycroft Scarlet is the nearest approach to this colour of any, it is dwarf and exceedingly free. Pride of Madford must not be omitted when dealing with bright coloured varieties, as when grown to give flower in quantity the florets reflex, showing the bright purple amaranth colour.

White flowered sorts are still unsurpassed for use at Christmas time. Madame Carnot, one of the finest exhibition varieties we have, is equally good to give flower in quantity. The white sport from Clinton Chalfont is a fac-simile of its parent in all except colour. This is snow white and a valuable addition. Isabel Williams has the colour of Elaine and the petal of Niveus. Mrs. Weeks should be more grown for this purpose than it is, as it is really very fine. The growth is all that could be wished, and the blooms extra fine in quality. Decidedly one of the best, if not absolutely the best of white flowering sorts for January, is the Queen. The growth is some-

what tall; this is really an advantage, as long stems can be cut with the blooms. Framfield Pink is quite the best in this section, the colour is quite warm as it were. Madeleine Davis is paler but chaste. —E. MOLYNEUX.

KALANCHOE FLAMMEA.

THIS comparatively new plant, that was exhibited at the Hybridisation Conference, from Kew, and of which the stock for distribution has since passed into the hands of Messrs. J. Veitch & Sons, Ltd., has a great future before it. There can be little doubt but that for general use it will become one of the most popular plants in cultivation, and that it will "catch on" with the public when it is placed before them by the market growers is equally certain. By the courtesy of Messrs. Veitch & Sons we are now enabled to give an illustration (fig. 4) of this plant. It clearly depicts the habit of growth, but does not afford a true conception of the bright beauty and exceptional attractiveness of the profusely borne flowers.

Relative to Kalanchoe flammea, "W. D." wrote in the *Journal of Horticulture* for July 13th, 1899, as follows:—"About four years ago seeds of this new species were presented to Kew by Miss Cole, who, with Mrs. Lort Phillips—according to the account given with the figure t. 7595 in the 'Botanical Magazine'—collected it in Somaliland. It flowered for the first time at Kew in 1897, and was then seen to be by far the most ornamental of the Kalanchoes in cultivation, and was considered to be one of the best indoor plants for general work introduced of late years, a future being predicted for it equal to that enjoyed by some of the most useful market plants. A good quantity of seed was ripened in 1897, and sown eighteen months ago, and from that seed several large plants flowered. It is of easy cultivation. The Kew plants vary in height from 15 inches to 2½ feet, and are surmounted with heads of bright red flowers, the heads of flowers ranging from 9 inches to 15 inches across. They grow well in a cool greenhouse, and can be finished in pots from 3 to 6 inches in diameter. When young they may be stopped once, or allowed to grow with a single stem until they flower. A mixture of loam, leaf mould, and sand is a suitable compost, and propagation may be effected either by cuttings or seeds. The flowers last in good condition from six to eight weeks."

GINKGO BILOBA.

FOR the vicinity of towns or smoky districts probably no tree is better adapted than this Conifer, which is the sole remaining member of a genus which was in former ages spread over the whole of the temperate and warmer parts of the earth; fossil specimens of Ginkgo being comparatively abundant in various parts, and are practically identical with the only representative of their race.

It is a native of China, and, though often given as a native of Japan, it is only found near temples in this latter country, where it has evidently been planted. Though very tenacious of life, and enduring smoke and dust as well, or even better than, any other tree, it is not very largely planted, probably because it is slow of growth and does not make a large tree in a comparatively short time. In a young state it is an upright, straight-stemmed plant with a few short side branches, but when older it forms a spreading head and makes a distinct looking, handsome specimen.

The name of the Maidenhair Tree applied to it has been taken from the resemblance the leaves bear in shape to the separate pinnae of the Maidenhair Fern, but the likeness is only in shape, the leaves of the Ginkgo being 2 or 3 inches across, two-lobed, and thick and leathery in texture. In general appearance it is unlike any other Conifer, being one of the few deciduous ones, but the flowers and fruit are very like those of some of the Taxaceae.

The Ginkgo, or, as it is also popularly designated, *Salisburia adiantifolia*, is said to be cultivated in China and Japan for the sake of its fruits, which are stated to be poisonous when raw, but sweet and edible when roasted. The wood is of a yellowish colour, fairly hard, easy to work, and takes a very fine polish.—C.

IMPROVEMENT IN QUALITY AND GERMINATING POWER OF SEEDS.

—We learn that the consulting botanist of the Royal Agricultural Society has reported that the superior quality of seeds examined and tested during 1898 has been maintained during 1899. The more important Grass and Clover seeds have reached a germination of over 90 per cent. Only one case of dodder in Clover seed was observed. In this connection it may be noted that the President of the Board of Agriculture is reported to be arranging for the appointment of a departmental Committee to consider the question of establishing machinery for testing the quality and vitality of seeds.

LONDON GARDENS OVER FIFTY YEARS.

No. 17.

PROBABLY you could not have found, forty or fifty years ago, a pleasanter spot for a stroll than amongst the market gardens and nurseries of Sand's End, Fulham. These grounds, and sundry old-fashioned houses having large private gardens, occupied the space between the King's Road and the Thames, ending near the bridge. It was not long before her Majesty came to the throne that the king's private road to Fulham was thrown open; up to 1830, no vehicles could pass except by tickets of admission, and from Buckingham Palace to its termination there were placed no fewer than six gates or bars. Sand's End, which some think named after Lord Sandys of Chelsea, but in fact we cannot tell, was not more than a half-hour's walk distant from Belgravia; on a bicycle ten minutes would have sufficed to carry one there. But, on such a machine, people could not then have got along the narrow footpaths or lanes amongst the gardens, which are now merely memories, for it is absorbed into London. Since 1837 the growth of Fulham is very marked, this suburb having advanced from 12,000 to 114,000 inhabitants.

Proceeding westward from Chelsea, and leaving behind us the former site of famous (or infamous) Cremorne, also the establishments of several nurserymen already mentioned, we come to Stanley House. It has a history connecting it with the Gorges, the Stanleys, and others of note; to the gardener it may recall the Countess of Strathmore. This lady distinguished herself by her love of horticulture in the reign of George III. At this mansion she built a number of conservatories, and was gathering a large collection of exotics, when her home was broken up by marriage with a scoundrel named Bowen. Crossing the bridge, our approach to the gardens was soon intimated by a tavern bearing the significant motto of the "Hand and Flower." This might indicate some time the extensive culture of flowers in the locality, but in my experience it chiefly produced vegetables and fruit, Sand's End, like the rest of Fulham, sending formerly large supplies of both to the markets nearly all the year, for they managed to have a quick succession of crops.

Notable amongst the gardeners of the place were Steel, Matyear, and the Bagleys, who had also land in other districts. It was a sight not to be forgotten, the lines of Apple and Plum trees, with their autumn show of fruit; frequently there was an undercrop of Currants, or vegetables, but all these orchards have been swept away. It was curious, that along some of the hedges the Crab or wild Apple showed conspicuously beside the Sloe and Whitethorn, with occasional dwarfed Oak and Holly. Some of these gardens had no protection of hedges, but were bordered by narrow ditches; they seemed exposed too much, especially when the ground happened to be thickly covered with hand-glasses covering Cucumbers or small salad, and so in peril of stones, suffering too in hailstorms.

Going along what used to be known as Bagley's Lane, Sand's End, some years ago, on a June morning, I witnessed a remarkable display of the insect called the Rose beetle, also *Cetonia aurata*. It is a beautiful beetle, of golden hue, but a mischievous species, though perhaps not generally recognised as a garden foe. The English name was given because it has been seen haunting the Rose; in this case the attraction was a tall Privet hedge just in bloom, and it is no exaggeration to say there were hundreds upon the wing in daylight. They have been noticed to attack the flowers of the Strawberry with their trenchant jaws, also those of the Turnip reserved for seed. Less observable are the operations of the grub, which resembles that of the cockchafer, and preys upon the roots of many plants, living two years in its larval stage.

Peterborough House, between Sand's End and Parson's Green,

claims a short notice. It was famous for its trees and flowers. A friend says it has as yet escaped demolition; no doubt its gardens are diminished. Faulkner, writing of Fulham, remarked that the place had "decayed" since last century; if so, it underwent a change for the better afterwards. One of the marvels of Peterborough House was a Tulip Tree, 76 feet in height and 5 yards in circumference, since dead. When I visited Sand's End, about 1877, the gardens of this house were under the care of Mr. Roberts, who delighted to exhibit a collection of the old border flowers; he had also many medicinal plants. Forcing was specially attended to; thus he provided Cucumbers and French Beans all the year round. Nearer the Thames, Broomhouse Lane recalls the fact that in the olden time a stretch of land belonging to the "Broomhouses" was covered with the "bonny Broom." Part of this land became market gardens, then was built over. The neighbourhood of Sand's End has had its share of aristocratic visitors of late years, who frequent Hurlingham and its park.

But, to gardeners generally the centre of attraction at Fulham was its famous nursery, one of those London establishments which could show a long and interesting record. This has now disappeared, though part of its site is still open ground. Through many years it belonged to the Osborns, so was often called by their name towards the close. That of "Fulham Nursery" seems sometimes to have been applied to that of Mr. Dancer, near Percy Cross. Few nurseries could boast of a better situation—the trees and plants were well sheltered, the soil all that could be wished. Through a succession of years the firm took a creditable position at shows and exhibitions. The nursery occupied about 20 acres, the greater part was planted with deciduous ornamental trees and evergreens, a portion being allotted to fruit trees. There was also additional ground at Sunbury used for Conifers, Roses, and miscellaneous plants. One of the facts that particularly impressed a visitor to the Fulham Nursery was its tidiness and order. About the houses, as a friend remarked a few years since, they were divisible into three groups. Some had an unmistakeable appearance of old age, they had done long service; and some again, if not venerable, were middle aged. Besides these were others, evidently strong and youthful, which had their work before them, exhibiting the latest improvements.

The exact date is doubtful, but the nursery was certainly opened early in Anne's reign by Christopher Gray, presumably one of the Scotchmen to whom horticulture owes so much. He was able in 1740 to print a list of the trees and plants he had at Fulham. Loudon and others have stated Gray had the first British *Magnolia grandiflora*. This has recently been questioned, and a claim made for one of older date in the West of England. Certainly one of the most notable trees in the nursery was a big specimen of *Magnolia Thompsoniana*. From Gray the nursery passed to Burchall, then to a firm of three persons, finally to the Osborn family. Mr. Robert Osborn, who became proprietor in 1877, was the grandson of the first of the Osborns. The ground had then been diminished, and in 1882 the few acres left were taken by Messrs. Veitch & Sons.

Many rare plants were sent to the Fulham Nursery by Messrs. Garden, Catesby, Colliuson, and Miller, or other celebrated collectors, and it had a large number of Bishop Compton's exotics. One of the remarkable objects was the Fulham Oak, a curious variety of the tree, which had a resemblance to another sport of Nature, the Locombe Oak. Seedlings from the Fulham Oak reverted to the usual type, so it has always been propagated by grafting. There were here fine examples of *Sophora pendula* and *Celtis occidentalis*, and one of the houses displayed under the stage a huge mass of the old Cape plant, *Anomatheca cruenta*, laden with deep crimson flowers. Several of the houses, even till a recent date, had a splendid show of Palms and Ferns.—J. R. S. C.

FIG. 4.—KALANCHOE FLAMMEA.

COMMERCIAL GARDENING,—No. 1.

THE notes on the expansion of the hothouse industry published in the *Journal of Horticulture* last year (page 268, September 28th), which were taken from Mr. W. E. Bear's report on "Flower and Fruit Farming in England," would, no doubt, cause a certain amount of surprise to those readers who know nothing of the hundreds of acres of glass houses round London, devoted to the production of fruit, flowers, and vegetables for market.

There are hundreds of small growers scattered all over England, who have never had the opportunity of visiting districts like Worthing, Turnford, Ponders End, or Bexley Heath. To visit these places, and the large establishments situated there, is often one of their greatest desires, but it is another matter to try to satisfy their wish. They find that the large growers are either too busy or do not care about visitors going round the nursery, and consequently it is only a few that know the almost clockwork methods which some of our best growers follow, and the splendid way in which their crops are grown. Knowing, therefore, the difficulties which stand in the way of your readers paying "visits," the writer (who has long been a worker in some busy hives of industry) thinks perhaps a few articles on the methods of market growers may prove useful to them.

HOW THEY GROW CUCUMBERS.

There are two kinds of houses that "the trade" build in which to grow Cucumbers, one 12 feet and the other 15 feet in width, and any length from 50 to 300 or more feet. The 12 feet wide houses are thought to be the best suited for those who have to grow Cucumbers in a cold and exposed situation, but there is no doubt that the larger houses are more useful and profitable, and cost very little more to build.

The big growers build their houses in blocks—i.e., instead of each house being separated from the next by a partition wall, the whole block, which may consist of five or fifty houses, have no partitions between them, but the gutter boards rest on wood piers. There are very few growers now who use more than four rows of 4-inch pipes to each house, even when the house is 15 feet in width. The cost of a 12 feet wide Cucumber house will be from 12s. to 14s. per foot run to build, while those 15 feet in width can be built at a cost of from 14s. to 16s.

RETURN IN CROP FOR OUTLAY.

No doubt the figures we shall give under this head will be open to criticism, for many growers can no doubt show a greater return both in the quantity of fruit and the price returned for them. We shall, however, give what some crops realised, the number of plants grown being 6000.

Most market growers endeavour to grow at least two crops of Cucumbers in one year. The first plants are obtained from seed sown now, and they fruit from March till the end of June; the next batch is sown the first week in June, and planted out between the old plants as soon as they are ready. A good average crop for the first set of plants will be from three to four dozen to each plant, and from the second crop from two to two and a half dozen to the plant. The latter are planted $2\frac{1}{2}$ feet apart, and as the fruit sold in the market will fetch on an average 2s. a dozen, it is not a hard matter to find out what one is likely to realise from a house of "Cues." Of course there is also the catch crop to consider, for market growers who have 12 feet wide houses grow four rows of French Beans in them, while two rows of early Tomatoes are grown down the centre of the larger houses. Both Beans and Tomatoes are planted out or potted at the same time as the Cucumbers are planted. The Beans are over in a month from planting, the Tomatoes in ten weeks.

RAISING PLANTS.

Nearly all Cucumber plants grown for market work are raised from seeds. The seed, as above indicated, should be sown at once, if fruit be wanted at the end of March. Very little is gained by very early sowing, for the day of big prices for Cucumbers is past, and what may be gained now by getting the fruit a week or fortnight earlier than the end of March is not worth having, as the extra fuel required often costs more than the profit will amount to. Nearly all market growers sow the Cucumber seeds in 48's or 5-inch pots. The soil used is a mixture of three parts turfy loam and one part of decayed farmyard manure. Turf that has been stacked long enough for the grass to decay is found most suitable. The 48's should be clean, and each of them must have a crock put in it, and over this about an inch of rough soil. On the top of the rough soil place about an inch of prepared soil, and then press one seed into the centre and just cover it. After the sowing is finished give the soil a good soaking of water, and then place the pots in heat.

It is of no use to try to induce Cucumber seeds to germinate in a low temperature. They will not grow, but rot. The temperature most suitable for germination is 70° F. by night and 80° to 85° by day

with sun heat. On very cold nights the temperature may be allowed to fall to 60°, and no harm will accrue, but the temperature first named is the one to aim for.

After germination has taken place and the seed leaves are formed, from 65° at night to 85° by day will suit them well. Growers not provided with a propagating house no doubt will find it difficult to obtain the temperatures named. There are two ways of getting over this difficulty. The first is to make up a small hotbed in the glass house, put a garden frame and light on it, and place the pots inside; the second plan is to sow in small 60's, and place them inside 48's or 32's, and stand the latter on the hot-water pipes, covering each pot with a piece of glass. The plants in the 60's can be transferred to 48's as soon as they are large enough.

TREATMENT OF THE SEEDLINGS.

When the seedling Cucumbers raised in 48's are big enough, the space left at sowing must be filled to within half an inch of the top of the pot with prepared soil. This operation is best performed when the plants have two fully developed seed leaves, and the first rough leaf is about 2 inches across it. Soil similar to that used for the sowing should be used, only have it more lumpy. Do not press the soil when tending at all firmly, and give water carefully until the new roots have begun to extend freely in the new soil. The temperature at this stage should be 65° at night and 80° by day. The atmosphere must be kept moist by judicious damping, and when the plants are large enough they must be secured to stakes.—TOM SLOWMAN.

EARLY PEAS.

In large establishments Peas cannot be had too early, and various means are adopted for advancing the crop. Many amateurs, too, adopt means for having an early supply.

November-sown Peas sometimes come in the earliest, and in other cases they are behind those sown in spring. If outdoor culture is exclusively followed, the autumn-sown Peas might be the first in most instances; but if a little extra attention be given to spring-sown Peas they will be the more satisfactory. I think it would astonish many if it was only known the quantity of seed that is lost through various causes by November sowing, and the patchy rows we often see in spring promise anything but a full and abundant crop. Mice and other vermin are more destructive on these than those sown at any other time, and it is generally before the growths come through the soil that the injury is done. From this it may be inferred that if early Peas were sown under protection, and planted after they had grown a few inches, losses on blank rows would be nearly unknown. This is my opinion, and of all ways of forwarding early Peas I think there is none better than sowing the seeds under cover and planting out.

I have tried many ways of raising young Pea plants—such as sowing them in turves, in tiles, old waterspouts, and boxes, but I never found them do so well as in 3-inch pots. Sowings made in two or three hundred of these (I have to cater for a large family) supply plants to make several fine rows. No drainage is put in the pots, but a little rough manure is placed at the bottom of each, and then rich soil is rammed firmly over this until the pot is about three parts full, when from eight to twelve Peas are put in each and covered with a little more of the soil. They are then placed closely together in a cold frame or cool house, and no water is given until the growths are seen. These soon appear, and water is supplied afterwards as it may be required. They are placed as near the glass as possible, but never in forcing heat, as this would weaken the growths. Air is admitted on all favourable occasions until they are large enough, and the weather permits of their being planted out.

When the time comes for planting the pots are well filled with healthy roots, and the work is done without injuring a leaf or root. All our best spring and early summer Peas were raised in this way last year, and I never had better. The labour required is inconsiderable compared with the advantages. In planting we do not place the potfuls as close together as they will stand, but each little tuft is planted about 6 inches from the other. Before they come into pod they look as if they were or had been originally packed in close together. If a little old potting soil can be placed against the roots at planting time it assists them in growing. The stakes are inserted into them at once, and if the situation is bleak or the weather cold a few Fir branches or Laurel trimmings are put in here and there for shelter.

With valuable Peas it is a bad plan to trust the seed in the ground early in the season, as from various causes many may fail; but if the plants are raised in pots all dangers of the kind cease. In fact, all our new Peas are raised in this way, whether they are wanted in spring, summer, or autumn, as many of them can only be had in small quantities.—K. G.

RECENT WEATHER IN LONDON.—The weather in London during the past few days has been very changeable. On Sunday morning it rained heavily, but the sun shone at mid-day and during the afternoon, and was followed by a frosty night. Precisely the same conditions prevailed on Monday until the evening, when rain again fell. Tuesday was showery, but cleared at night, and the stars shone brightly and clearly. Wednesday opened wet.

WEATHER IN THE NORTH.—The weather of the week ending the 8th inst. has been variable, and for the greater part disagreeably dull and wet. On the morning of the 5th, and again on the 7th and 8th, there was frost of from 3° to 5°, but the afternoons and evenings invariably brought cold showers. The hills all round have been covered with snow.—B. D., *S. Perthshire*.

YUCCAS.—*Apr*opos of "A.'s" interesting and instructive notes (page 569) respecting the decorative value of these plants, I am reminded of the value of several species for flower garden vases, tubs, or other suitable receptacles on the terrace. For such purposes one of the most imposing is the Adam's Needle, *Y. gloriosa*. The more graceful, however, for pedestal vases is *recurvifolia* or *pendula*, while *aloifolia*, as referred to by "A.," forms a noble and graceful object during the summer months in sheltered positions; the same remarks apply also to *aloifolia variegata*, *sperba*, and *serrulata*. It is said that *Yuccas* seldom perfect seed in this country, excepting, perhaps the profusely flowering *filamentosa*, the most commonly grown in the flower garden. The sterility in question has been accounted for by an American entomologist as owing to the absence in this country of a particular kind of moth, a native of South America, and which there aids the fertilisation of the flowers. One of the most prolific species is *acuminata*, commonly called the Spanish Bayonet, on account of its long, stiff, and sharp pointed leaves.—W. G.

EUCALYPTUS OCCIDENTALIS.—This is one of the few species of *Eucalyptus* that can be got to flower in a small state, and although the flowers individually are not very showy, the freedom with which they are produced makes the plant quite attractive. A specimen is now flowering in the Mexican house at Kew; it is about 12 feet high, the upper half being smothered with buds and flowers. The plant in question has been pruned to keep the head in shape, and possibly this somewhat hard pruning has something to do with its freedom of flowering. The branches are slender, and clothed with thick green leaves, 2 to 4 inches long. The flowers are creamy white, and borne in umbels of seven or more from the nodes on old and new wood. The chief attraction in the flowers is the large number of stiff thread-like stamens, which gives them a brush-like appearance. Like most of the other members of the family, this is an Australian plant, and grows well in any good soil. It is growing in an intermediate house at Kew, but a cold greenhouse is quite adapted for its cultivation.—D.

EARLY PEACHES.—Where Peach and Nectarine trees are started at the new year, or before, with a view of getting ripe fruit in April, the chances of a good and well-finished crop depend considerably on how the trees have been treated previously of course, but no matter how well ripened or how healthy the trees may be, much depends on their treatment in the earliest stages of forcing. Regarding temperature, it has come to be well understood that a low and gradually increasing one is the safest, but this is only one part of the work, and a more rational method of watering is much to be desired. Watering at the root may be said to be fairly well carried out, but to keep on throwing moisture about the house and all over the trees is entirely a mistaken idea. On fine days, when a liberal amount of air can be admitted, there is no harm, but the reverse, in gently dewing over the trees, as it softens the buds and makes them break kindly, as well as making any chance insect uncomfortable, but too much of it softens and weakens the growth, making it pale-coloured and yellow. Even later trees are not helped by these regular douches, often of cold water, but it is infinitely worse for the early ones. As in every other detail of culture, care and observation are necessary.—H. R. R.

PRESENTATION TO MR. HERRIN.—On the occasion of the retirement of this well known and respected gardener from Dropmore, Maidenhead, he was presented on the 29th ult. with a fourteen-day timepiece. This was subscribed for by the employés in Dropmore Gardens, all of whom entertain very great respect for their chief.

CALADIUM ESCULENTUM.—Plans will have to be made soon for bedding out and other arrangements in the flower garden, and propagation of various kinds of plants will soon have to be taken in hand. For those who like a fine-foliaged and easily grown plant for the purpose of summer decoration this fine Aroid will be suitable. At this time of year dry roots are easily procurable, and may be potted singly and placed into a newly started vinery or Peach house where the leaves will soon push up and the plant will be ready for putting out by the middle of June. They will make a fine show all the summer, and may be lifted again at the end of October.—C. HALL.

ANTHOLYZA ÆTHIOPICA.—This South African bulbous plant is closely allied to *Gladiolus*, and in habit is very similar to some of the species of that genus. In the south-west counties it is hardy, and can be left out all winter; but in most places, owing to its habit of commencing growth early, it should be grown in the greenhouse, or at any rate wintered indoors. When treated solely as a greenhouse plant it should be started into growth in October; it will then be at its best about Christmas or early in January, a time when the fresh, light green foliage is greatly appreciated. The flowers are rather small, but borne in considerable numbers on stout scapes well above the foliage. They are reddish brown in colour. In addition to the type there is a variety called *bicolor*, which, to some people, would be the better plant, being dwarfer, more compact, and flowering equally as well. Besides being a good pot plant, it can be grown planted in a border of loam. In such a place it soon reaches a good sized mass.—D.

HESSLE GARDENERS' SOCIETY.—A fortnightly meeting of the above Society was held in the Parish School Room, December 19th; Mr. Mason occupied the chair. A very interesting and suggestive paper on the culture of Peaches and Nectarines under glass was read by Mr. Reid, Swanland Manor Gardens, Brough. His thoroughly practical remarks were much appreciated. The essayist recommended systematic waterings throughout the whole season, and at no time must the borders be allowed to become dry, otherwise the casting of buds would ensue. Pruning of Peach trees immediately after the last fruit has been gathered was an important item in their culture strongly advocated by the essayist. This work being completed they have a far better chance of ripening the wood, so that with abundance of air the trees will produce sound matured fortified growths to commence with the ensuing season. Red spider and other insect pests are very troublesome, but with regular syringing and good general management they may be easily kept at bay. A vote of thanks to the Chairman and essayist terminated an instructive evening.—J. F. D., *Yorks*.

"FRUIT FARMING FOR PROFIT."—Mr. George Banyard, V.M.H., sends us a copy of the Fourth Edition of his Practical Treatise on the above important subject. "Practical" it undoubtedly is, and the best evidence of its value and acceptability is that of the continuous demand. The work appears to have been largely rewritten, and is brought quite up to date in the selection of varieties of fruits for planting, some of the older having been superseded by recent additions. Nowhere can the most advanced methods of Kentish fruit growing be found so completely and accurately described as in this well printed and substantially bound work of 200 pages. In a chapter on planting it is truly said, "The holes dug for planting in wet soil, become so many traps for the water, and if the soil is not particularly good the roots do not travel from the original hole, and the trees come to grief in a few years." The author believes in and advocates thorough work: he gives an example of contract planting thus—"On removing the dead trees it was found that in order to make a sightly job the planter had sunk the tall trees deeply in the ground to make the heads come level: he had literally dug graves for them. The trees were a bad lot to begin with, being all heights and sizes." Owners of plantations have usually to pay dearly for so-called cheap trees and shuffling work. Planting may be done, we are correctly told, "in November and all through the winter till March, the main point being to have the ground in good working order." The work contains plans and illustrations, and cannot fail to be useful to growers of fruit. It is a handy half-crown book, and well worth the money, published by Mr. W. S. Vivish, King Street, Maidstone.

— **DEATH OF MRS. WM. PAUL.**—We learn with deep regret of the death on the 7th inst. of Mrs. W. Paul, wife of Mr. Wm. Paul, F.L.S., V.M.H., Waltham Cross. The deceased was in the sixty-seventh year of her age. Readers of the *Journal of Horticulture* will unite with us in offering sincere condolences to Mr. W. Paul in his great bereavement.

— **ROYAL METEOROLOGICAL SOCIETY.**—The annual general meeting of the Society will be held at the Institution of Civil Engineers, Great George Street, Westminster, on Wednesday, the 17th inst., at 7.45 P.M., when the report of the Council will be read, the election of officers and Council for the ensuing year will take place, and the President, Mr. F. Campbell Bayard, LL.M., will deliver an address on "A New Discussion of the Greenwich Meteorological Observations, 1848-1898," which will be illustrated by lantern slides. The above meeting will be preceded by an ordinary meeting, which will commence at 7.30 P.M.

— **STARTING POTATOES PRIOR TO PLANTING.**—We have several times suggested the sprouting of Potatoes under glass to obtain earlier crops, as we had practised it with success more than thirty years ago. The Kansas Experiment Station tried it some time back, planting whole Potatoes in a box of sand on February 23rd. The blossom end was left up, and about one-fourth of the Potatoes exposed to the sunlight at a temperature of 50° to 60°. Vigorous sprouts soon started, and, says the "American Agriculturist," on March 22nd they were planted in furrows just as they stood in the boxes. Similar rows of Potatoes from the storage room, not sprouted, were planted at the same time. The sprouted Potatoes started ahead, and kept ahead all the time. On June 1st the sprouted Potatoes showed excellent young table Potatoes in the hill; June 16th they were still ahead, and when dug on July 24th the sand-sprouted Potatoes had better tubers and gave 10 per cent. larger yield. Later experiments, conducted by the same experts, showed similar results.

— **BAMBUSA VULGARIS STRIATA.**—By reason of its bright-coloured stems this is one of the showiest of the several Bamboos cultivated indoors in this country. For a number of years it was accorded specific rank, and was then known as *B. striata*; it is now, however, admitted to be a variety of the giant *B. vulgaris*. It was originally introduced from China, but is now sent home from a number of places, having been pretty widely distributed in the tropics. Although when planted out in a border of rich soil in a tropical house it attains a height of 20 feet, it makes a handsome plant of half that height in a pot, and for ordinary establishments would be found more useful grown in that manner. In general appearance it is of somewhat loose habit, with numerous branches on the upper portion of the stem bearing a quantity of bright green leaves varying from 5 to 8 inches long and from 1 to 2 inches wide. As before stated, the stems are the most ornamental part of the plant, being bright, glossy yellow, striated with green. It requires the temperature of a stove and should be well fed while growing. A few plants in pots would be found useful for house decoration.—K.

— **GRAND YORKSHIRE GALA.**—The annual meeting of guarantors and life members of the Grand Yorkshire Gala was held last week at Harker's Hotel, York. Alderman Sir C. A. Milward presided. The Chairman said it was a matter of sincere congratulation to them all that last year's Gala was one of the most prosperous in the annals of the institution, and they could only hope that the forthcoming Gala would be equally as prosperous, although they had not the prospect of a good start. He was afraid that the holding of the Royal Agricultural Society's Show in the following week would materially affect the attendance at the Gala. He had to commence the business by proposing that the Lord Mayor be elected President for the ensuing year. Mr. Alderman Border seconded the motion, and said they hoped it would not be twelve years again before the Lord Mayor again presided over the destinies of the Grand Yorkshire Gala. The resolution was passed unanimously. The Lord Mayor then proposed that Sir Christopher Milward be elected Chairman of the Council. Mr. Alderman Border said he would be glad to render any assistance he could in relieving the Chairman of duties at night meetings. Sir Christopher said he would again accept the office if he were relieved of night work during the months of January, February, and March. Mr. Alderman Border was re-elected Vice-Chairman; Mr. Jos. Wilkinson was re-elected Treasurer; Mr. Simmons was unanimously re-elected Secretary; Messrs. Pearson and Taylor were re-elected Auditors. The following grants were made:—£650 for the floral fête, £230 for music, £120 for fireworks, £60 for balloon ascents, and £175 for amusements.

— **STUDY THE APPLE MARKET.**—Growing fruit is one thing and marketing it seems quite another, yet both should receive watchful care until the fruit is safely off and the best market price in cash is in the pocket. Of all the shortcomings of the orchardist, says "T. L. K." in a transatlantic contemporary, there is none just now so prominent as poor marketing. The Apple has come to be a standard agricultural product, both for home consumption and foreign markets, and the Apple dealers commence early in the season and canvass the Apple sections from month to month, making careful estimates until Apple picking, when they are perfectly posted on the quantity and quality of the crop, as well as to foreign demand. This should be, and might be as thoroughly understood by the well-read orchardist as by the dealer; and when this part of the business is understood, the orchardist can put a price on his fruit, as well as to wait for the dealer to make a quotation for him.

— **YOUNG PINES AND FOREST FIRES.**—Young long-leaf Pines, according to Mr. Pinchot of the U.S. Department of Agriculture, protect themselves against forest fires in a most interesting and remarkable manner. For four or five years the stems of the infant trees attain a height of only as many inches above the soil. During this time their bark is extraordinarily thick, and that alone gives some protection. But in addition, the long needles spring up above the stem, and then bend over on all sides "in a green cascade which falls to the ground in a circle about the seedling." This green barrier can with difficulty be made to burn, while the shade that it casts prevents inflammable grass from growing near the protected stem. Mr. Pinchot thinks that it is owing to this peculiar system of self-protection which the Pine seedlings have developed that the growth of evergreen Oaks in Florida has been restricted in regions where fires have raged, while pure Pine forests have taken their place.

— **GAS-WATER AS A MANURE.**—About sixty years ago interesting experiments were made with gas-water or ammoniacal liquor as a manurial agent for the destruction of worms on lawns, and also for hastening the decomposition of heaps of vegetable matter. As an insecticide it was also used by diluting it with a certain proportion of water. Previously, its manurial and other properties, as indicated, were unknown, and in London it was consigned to the Thames, to the destruction of the fish. As a manure for the Brassica tribe and Grass its effects were most pronounced, care being taken to apply it at a suitable strength. If lawns are thus dressed with it, any moss would be quickly destroyed, while the verdure of the grass would be intensified, as well as the crop in weight. It made the stalks and leaves of cereals grow luxuriantly, but without sufficient stability in the former, hence requiring some other suitable element added. Sawdust saturated with the liquor quickly decomposed, and thus formed a good manure. Of late years comparatively little notice has been given to gas-water as a manure, probably owing to the subsequent wide extension of the numerous artificial manures. It would, however, be interesting to learn if gas-water is still used to any extent at the present time.—G.

For the most part a dull dark week, with frost on three mornings. Rain fell on five days. Monday, January 1st, was an exceptionally dark, foggy day.

THE ATMOSPHERE, AND THE ATMOSPHERIC FOOD OF PLANTS.

THOUGH this all-important subject has been treated from time to time in the *Journal of Horticulture*, we do not remember its having been presented more comprehensively and clearly than in a lecture by Professor Black, published among others some time since by the New Zealand Department of Agriculture, but only received by us a few weeks ago. It is reproduced with slight abridgement as follows:—

Of the seventy elements that, in various states of combination, make up the crust of the earth, thirteen enter into the composition of plants, and may therefore be regarded as plant food. Five of these are metals—viz., potassium, sodium, calcium (the metal in lime), magnesium, and iron. The other eight are non-metallic—viz., carbon, oxygen, hydrogen, nitrogen, chlorine, sulphur, phosphorus, and silicon. Of these, carbon is supplied almost exclusively by the air; nitrogen partly by the air, but mainly from the soil. All the others are supplied by the soil and water.

The atmospheric air is a mixture of various gases, of which nitrogen and oxygen are the most abundant, making up between them more than 98 per cent. of the whole. The carbonic acid, though amounting to only about 6 parts in 10,000 by weight, is of the very highest importance to plants; and there are small quantities of ammonia, nitric acid, and nitrous acid, all containing nitrogen; and, in the air of large manufacturing towns, sulphurous acid and sulphureted hydrogen. There is, of course, also the vapour of water, which is very variable in quantity, being evidently less abundant just after a three days' heavy rain than just before such an occurrence. Besides all these, there is another gas named argon, recently discovered in the air, and comprising about $\frac{1}{100}$ th of its total volume. Disregarding the small quantities of aqueous vapour, of argon, and of carbonic acid, and the other still rarer constituents named, we may take 100 gallons of air as containing 79 gallons of nitrogen and 21 gallons of oxygen; or, if we take it by weight instead of volume, 100 tons of air contains 77 tons of nitrogen and 23 tons of oxygen.

The proportion of carbonic acid gas in the air may be stated as 4 gallons in 10,000 gallons of air, or about 6 tons in 10,000 tons of air. Small though this proportion of carbonic acid gas is, yet when the enormous quantity of atmospheric air is considered, it will be seen that the weight of this gas that rests on every acre of surface of land and sea all round the earth amounts to about 24 tons. The sources of this carbonic acid gas are varied. First, there is the breathing of animals. The exhaled air is mainly nitrogen and oxygen, but it also contains the vapour of water and about 4 per cent. of carbonic acid. It is therefore about one hundred times richer in carbonic acid gas than the inhaled air. This, therefore, is a constant and important source of the gas, as all animals of every sort and every size are busy all life long, night and day, asleep or awake, on land or in the sea or air, perpetually making carbonic acid gas. Secondly, the burning of fire is another productive source. A ton of West Coast coal in burning evolves about $2\frac{1}{2}$ tons, and the lignites from $1\frac{1}{2}$ to 2 tons, of carbonic acid. Indeed 3 lbs. of carbon in every kind of fuel produces about 11 lbs. of this gas.

There are, thirdly, small contributions from what is called the burning of limestone. In this process (in which, however, nothing is burnt but the fuel that heats the limestone) every 100 tons of pure limestone evolves 44 tons of carbonic acid gas, and leaves a residue of 56 tons of burnt lime or quicklime in the kiln. Fourthly, in the process of fermentation of the sugar in brewing, wine making, whisky, &c., 180 lbs. of sugar splits up into 92 lbs. of alcohol and 88 lbs. of carbonic acid. There are also, fifthly, notable quantities of this gas produced by the decay or oxidation of dead organic remains—the bodies of plants and animals; and there is, lastly, the most prolific source of all in the exhalations issuing from the craters and crevices of extant and extinct volcanoes, and from numerous other fissures communicating with the interior of the earth. Those that best know tell us that from this source alone there is probably seven times as much carbonic acid gas heaved into the atmosphere as there is produced by all the other sources put together. Of the atmospheric gases, taking an equal bulk of each, carbonic acid is the heaviest, argon next, oxygen next, and then nitrogen. The numbers representing the relative weights of these, in the order in which they are named above, are 22, 20, 16, and 14 respectively; aqueous vapour is 9, and ammonia $8\frac{1}{2}$.

If in the atmosphere these gases behaved like a mixture of liquids such as, say, mercury, water, and ether, of which the heaviest would go to the bottom, the others resting on it in the order of their specific gravity, we should have all the heavy carbonic acid settling down into the valleys and low-lying lands and plains, and covering these with a deadly pall to the depth of many feet. The waters of the oceans would in that case also dissolve a large quantity of the gas, and life on land or sea would be impossible. Such, however, is not the case, for, in obedience to the law of the diffusion of gases, all gases that do not act chemically on each other distribute themselves uniformly throughout the whole space which they jointly occupy. By the operation of this law (which is not really, though apparently, inconsistent with the law of gravitation) the carbonic acid produced at the

surface of the ground rapidly diffuses itself away up all through the atmosphere, and maintains everywhere its proportion of about 4 gallons in every 10,000 gallons of air.

(To be continued.)

PRUNING.

MUCH has been written on this important operation in gardening, much has been taught, and much either apparently forgotten by some performers with the knife or misunderstood. Pruning may be divided into two distinct methods, the one carried out under the cut and dried formula of "prune to a given number of buds or eyes," as if regardless of the future; the other in which thought and care for the after-growth guide the action of the operator. When there is a great amount of pruning to be done, it may be impossible to avoid a certain proportion from being carried out in a mechanical manner; yet who shall say that this machine-like method has not gone too far in many instances? It is all too frequently seen in the persistent stumping back of trees growing in rich soil, until there is nothing but a thicket of useless growth each season, instead of a crop of health-giving fruit. No trouble appears to be taken by some persons to thin-out and expose the leaves on what ought to be the main branches to the influence of light and air; yet there are thousands of trees that have no distinct main branches, but have been distorted into dense bushes, and the trimming of these into form yearly is called "pruning."

A gardener found in a new situation some old espalier Apples, which had been innocent of fruit for years. They bore heavy crops of rampant stems that had been closely cut off and burned time after time. No amount of persuasion would induce the owner to part with these treasured trees, so there was nothing for it but to make the best of them. By leaving a few of the strong shoots along the top tier of branches about 15 inches asunder, just taking off the unripened tips. The second spring afterwards, the shoots so treated were wreathed with blossom buds, and, as the weather was favourable for setting excellent fruit followed. Nor was this all. The lower branches gradually improved, as if steadily invigorated by giving the "old stagers" their heads. True the clusters of exhausted spurs were thinned, and the branches cleansed, and those that remained gave what gardeners would call a "good sprinkling" of Apples. It might have been better to have uprooted these old trees and planted young ones, but in this case as in many others the gardener was not a free agent. The owner would not hear of parting with his gnarled friends, and there they remain, and nothing that the "new" gardener did gave more pleasure than the attention he so usefully applied to the old family favourites.

This desire of owners to retain almost useless fruit-bearers in their gardens opens up another part of the subject. In the matter of Vines it would be hard to say how many vineries in this country would be made vastly more profitable if the worn-out occupants were consigned to the rubbish fire and young thrifty canes planted in their stead. But if the old Vines must perforce remain, is the best always made of them? We read from time to time of the rejuvenation of ancient Vines by the renewal of borders and such-like commendable means, but cases are not at all rare where the stereotyped habit of pruning to a certain number of buds at the base of the current season's growth is continued. The same decrepit rods remain year after year, their curled and twisted spurs weakening accordingly, some dying, others dwindling until they have scarcely strength with which to start into growth. Would it not be better to vary the procedure for a time, by pruning to some of the best buds on the lateral shoots, and also by starting young canes from the base, so that these might afterwards take the place of the veterans, which could be gradually cut out to make room for them? I am convinced that better crops of Grapes of finer quality might be obtained by carrying out these simple methods.

Returning to outdoor fruits, experience has proved conclusively that decided advantages are gained by keeping these thinly disposed, the removal of worn out branches, and inducing new ones to replace them. Take the case of Peaches on walls. I have seen old trees condemned, yet by careful treatment in this manner they have been made to render a good account of themselves for a number of years. I have also in mind a number of large Apple trees which were benefited in the same way, these, after a time, producing fruit which could not be regarded as discreditable if produced by much younger trees. I should like to uproot many old trees and plant young, also to have new ranges of vineries to plant, but have no such privilege. In the meantime, I try to make the best of what is obsolete, and remain—SUBMERGED.

ACACIA PUBESCENS.—There appears to be a slightly increased interest in the beautiful section of Acacias that are suitable for greenhouse culture, and this is one of the best of them. Foliage and flowers are alike extremely graceful, and it rapidly makes fine specimens. The flowers are produced in the earliest months of the year, and growth starts soon after. Quite a cool greenhouse with ample root moisture suits it well, and for the sake of making room, as well as the health of the plants, they may be stood outside from the end of May until October. Under these very simple conditions this useful plant thrives admirably.—B. S. E.

ANGRÆCUM PELLUCIDUM.

THIS is one of the Orchids one would like to see more plentiful, its beautiful flowers on the long pendulous leaves being quite distinct, and having a transparent appearance that called forth a very vigorous encomium from Dr. Lindley, who, according to Messrs. Veitch, remarked of this Orchid that "its flowers were as delicate and transparent as if they were flakes of snow fixed by frost in the very act of melting." The plant likes a hot, moist, and shady house, and, like most others of its kind, must never be dried at the roots. Small baskets and a compost of sphagnum moss and crocks suit it best.

CYPRIPEDIUMS.

No time should be lost in repotting any of the early winter flowering section that have passed their best. The plants, it should be noted, are usually growing more or less freely at the time the flowers are open, and soon take with a will to the new compost. This may consist of about equal portions of peat fibre, loam, and chopped moss, and a little limestone has been found by many cultivators to be advantageous when dealing with the *C. bellatulum* section. For the strong growers large pots may be used, and the roots should be well spread out, working the compost down between them, and watering soon after.

ONCIDIUM UNDULATUM.

The majority of this genus have flowers mostly yellow, though in some cases there are lovely combinations of other tints, and there is sufficient variety of form to prevent any likelihood of a charge of sameness being brought against them, a variety of colour is also desirable. This is found in the pretty species above named, rich tints of plum purple, brown and chocolate, with a little yellow or white on the petals being usual. It produces fine twining spikes in the way of those of *O. macranthum* from the centre of the young growth. It cannot be called a difficult Orchid to grow, but, like all in this section, must be kept cool and moist.

It has the habit of pushing one pseudo-bulb well above the last node, and when this begins to root the roots are, of course, considerably above the surface of the compost, rendering them an easy prey to slugs. If any of these are present the roots must be covered with a little new compost; or, better still, this may be placed about the pseudo-bulbs just before they begin to root. Naturally a strong-rooting kind, the pots must be fairly large, thoroughly drained, and the compost be rough and open. During the season of active growth a very large amount of moisture is needed, and while the spikes are forming these should be carefully protected from injury.

RESTING ORCHIDS.

What a sad misnomer is this term in many cases. With the idea of resting their plants, many cultivators are still in the habit of almost entirely cutting off the water supply, and allowing them to get into a more or less attenuated and shrivelled condition, that takes many weeks of attentive culture to set right again. Generalities are not always convincing, and I will mention a few plants that are often much overdried.

First there is the labiata section of Cattleyas. It is a mistake to think that because no outward signs of growth are apparent, that therefore none is going on. The flowers are forming in embryo, and the plumping of the basal buds is not by any means completed when the pseudo-bulbs finish swelling in summer and autumn; yet almost before they are finished the water supply is suddenly cut off, and the flowers are starved in the very earliest stages. I think I am not far wrong in saying that these lovely Orchids in the majority of instances are very much underwatered in autumn, and in the endeavour to plump them again are overwatered in spring. This often leads to the damping of new growths, which naturally have not the same stamina as those from plants that have not been allowed to shrivel.

In a less marked manner the same thing happens to Dendrobiums, especially those of an evergreen character. The deciduous kinds, if properly finished and ripened in autumn, can hardly be kept too dry at the roots from the time the last leaf falls until they are re-introduced to their growing quarters. The well known *Odontoglossum citrosum*, again, is best quite dry in winter, this being one of the few kinds that may be allowed to shrivel with impunity. But no other member of the genus will stand such treatment, though almost every one likes a resting season of longer or shorter duration.

The long dry season various Orchids have to pass through in their native habitats is advanced as an argument in favour of similar

treatment being accorded them under cultivation, but this theory is not altogether a good one. All plants of a Vanda-like habit, or nearly all, have to put up with far drier conditions of climate when growing wild than they are found to like at home in our houses, and many other instances might be cited. Plants have not the choice of their own growing quarters, and if by observation of their likes and dislikes we can improve these wildings it is far better than following Nature too implicitly.—H. R. R.

NOTES ON DENDROBIUMS.

CONTINUING my remarks on Dendrobiums from page 16, I may say that other kinds that will thrive with spectacle are *Hodgkinsoni*, one of Messrs. F. Sander & Co.'s recent introductions, and *Johnsonia*, which takes a very long rest. *D. amboinense* is a very remarkable plant that produces at various times of the year flowers which only remain fresh for a day or two, and it is for this reason we have never been able to exhibit it before the Orchid Committee of the Royal Horticultural Society. It was discovered by Henshall in Amboyna, and was flowered by Messrs. Rollisson at Tooting in 1856. Messrs. F. Sander & Co. imported a few plants about seven or eight years ago, one of which came under my care. We found it very difficult to grow satisfactorily. All the above, except *amboinense*, will stand fog.

Other useful New Guinea and Australian Dendrobes for autumn and winter flowering, that require similar treatment, are *bigibbum* (grand for Christmas), *canaliculatum*, *Phalaenopsis*, *stratiotes*, and *undulatum*. The flowers of the latter remain fresh for over three months. Most of the Indian Orchids, especially the Moulmein and Burmah species, require a long rest in a dry airy house to induce them to flower; but those enumerated must never be allowed to become dust dry.—F. J. THORNE.

AQUILEGIAS.

THE Aquilegas (fig. 5), or as they are more commonly called, "Columbines," are among the most useful and beautiful plants for adorning our gardens during the early summer months. They possess an elegance which only needs to be seen to be fully appreciated, especially with the long-spurred section, of which the well-known *Aquilegia chrysantha* may be regarded as typical, and which, when well established and covered with its myriads of blossoms, may take a place among the choicest perennials. These Aquilegas are easy to cultivate, and their best method of propagation is by seeds, which they yield abundantly. In the flower garden, where partial change is needed from the general run of bedding plants, the Columbines are specially adapted; and growing well in ordinary soil is only another point in their favour. They make a most pleasing bed alone, or they may with good effect be associated with annuals in the mixed border, or with some dwarf bedding plants.

It may not be altogether lost if I briefly cite some of the most showy members of the Columbine family, which by giving to each its average height and predominant colour, may tend to assist those desirous of embracing one of the most elegant groups of perennials.

A. ALPINA.

This is a showy species, growing from 1½ foot to 2 feet high and bearing showy blue flowers; a most desirable plant for the second row in the border or for the higher positions on the rockery. It succeeds well in ordinary sandy loam of good depth made fairly rich, and where possible comparatively moist. It inhabits high elevations in the European Alps, over which it is somewhat widely distributed. This must not be confounded with *A. vulgaris*, flowers of which are of a deeper purple-blue, though the characteristic distinction is in its longer stamens and larger flowers.

A. CALIFORNICA.

This is a most distinct and highly decorative species from the locality signified in its specific name, and which has, in conjunction with the yellow-flowered *chrysantha*, produced some chaste and elegant hybrids. It attains a height of 2½ feet, and produces flowers of a bright scarlet hue somewhat profusely. If only on account of its distinguishing colour it is entitled to a first place among choice hardy plants. When established it forms a compact handsome bush.

A. CHRYSANTHA.

This is one of the most showy and floriferous of all the Columbines, and one which when well established in a rich deep soil attains to a height of some 3 feet and nearly as much in diameter. It is at this stage, which under good cultivation may be reached in about three seasons, that they are admired by all who see them. There is no formality about them, but a natural grace and beauty which all may enjoy owing to their delicate and pleasing shades of colour. It is by letting them alone after being once well planted that they may be had in perfection. It is not uncommon for this

species to continue flowering for two or three months, and taking into consideration how charmingly its light golden flowers mingle with other shades of colour it at once stands forth as a valuable plant either in a cut state or for border decoration. I would not advise the planting of this species in shrubberies, for in almost every case it is sure to become crowded by stronger growers. Rather give it a good position in the open border or bed—a central

making it one of the most desirable plants for the rockery or for the front row in the border. It grows from 6 to 10 inches high, and should be planted on slightly elevated positions on an even surface. Anywhere in flower it is one of the most conspicuous of the alpine section, and inhabits the Altai Mountains. If disposed in small colonies on level surfaces of the rockery, where a good depth of sandy soil mingled with stones to keep it uniformly moist at the roots can be given it, it

FIG. 5.—AQUILEGIAS.

one if possible, where it will have ample room for free development. This species is better known than many, and is quite distinct from any other of this genus.

A. GLANDULOSA.

This is not only one of the most charming species of this genus, but it is at the same time one of the most exquisite of hardy perennials. No greater praise can be accorded it than this, and this is not more than it deserves; and the large handsome flowers, the sepals of which are of a deep rich blue, with pure white corolla,

will be found to thrive admirably. It deserves every attention, and well repays good cultivation.

A. SKINNERI.

In point of colour this is a very distinct species, the flowers being of an orange-red and slightly tipped with green at the mouth. It grows nearly or quite 3 feet high, though not so bushy or compact as some, but still very interesting and distinct; and then, apart from those above named, we find some useful plants in the form of vulgaris, both single and double. In the latter we have its double white form,

which is very useful in a cut state. *A. vulgaris caryophylloides* is also a double, and whose flowers are handsomely striped. *Witmaniana* has flowers of blue, violet, and white, and is a good useful border plant; while in *atrata* we have one of a vigorous constitution and deep reddish violet flowers. The foregoing are among the best of this very pleasing and free-flowering genus of hardy plants. There are, however, many more both of species and forms, and new varieties are continually coming in view. One of these, *grandiflora alba*, is a fine white with single flowers, good robust habit, 2 feet high, and a welcome addition to the list of good things.

A. CERULEA.

The Rocky Mountain Columbine is one of the choicest alpine which cannot be too highly recommended. Among hardy-plant, growers it is well known, and its unique beauty warmly appreciated. It grows freely in any warm sandy soil (here in passing I may remark that the Columbines as a whole object to stiff or cold soils), and grows about 18 inches high; the foliage assumes a deep glaucous hue, and is much divided. From the bushy rootstock arise the somewhat branching flower stems, on which are situate numbers of its charming blue-and-white flowers. These are erect, and display the flowers to advantage, a combination so charming in the soft blue of the sepals and pure white petals that it has been compared to "a large soft-coloured Clematis," and while I cannot discover the slightest resemblance, it must be regarded by all as one of the handsomest perennials. It flowers in early summer, and lasts a long time in perfection.

By saving a few seeds each year and sowing early in January an annual display of this charming plant may be guaranteed, and as I rest in the full belief that no one having once succeeded with it would care to be without it in future, it is deserving any care or extra attention to keep up a good supply. It is worthy of remark, however, that it is of easy culture as compared with some of the other rare species—a point considerably in its favour.—H.

SUPERIOR BLACK ALICANTE GRAPES.

I FORWARD a sample of Grapes. You will no doubt remember me writing to you two years ago under the *nom de plume* of "Young Grower," asking for advice as to the large number of stoneless berries in the Alicantes forwarded at the time. You will be pleased to hear that by carefully following your advice I have had scarcely a small berry the past two seasons, and the colour has also been better than before. It may interest you to know the number of prizes we have taken for Grapes during the five years I have had charge of the Vines.

PRIZES FOR GRAPES.

Year	1sts.	2nds.	3rds.	Total.
1895	6	7	3	16
1896	14	5	2	21
1897	11	6	4	21
1898	15	10	4	29
1899	9	14	1	24
	55	42	14	111

Also the following medals:—Two silver-gilts, one of them the "Jubilee" medal, of the N.C.S.; two silver-gilt Knightians and one silver of the R.H.S.; also a silver medal at Beckenham.

The prizes were taken at ten Societies' exhibitions. Best wishes for the new year.—WM. TAYLOR, *Tewkesbury Lodge, Forest Hill.*

[We respond with warm congratulations. The Grapes were splendid in size and uniformity of berries, and especially in quality. We have never tasted better Alicantes, and few as good. It will do no harm to repeat the advice we gave that seems to have been helpful, and it may possibly be helpful to others. It was given under the heading "Stoneless Grapes" as follows:—"Such splendid clusters would be highly creditable to an old grower if all the berries were the same size as one of them—namely, $4\frac{1}{4}$ inches in diameter and nearly round, or much rounder than those of Black Alicante usually are. This huge berry only contained three seeds, the majority, about half the size, containing, some two seeds, and others only one seed, while the too numerous smaller berries are seedless. As the border contains "plenty of lime rubbish," and has received in addition an annual dressing of lime, you do not think the lack of seeds is attributable to absence of lime; all the same, we should not hesitate to apply 4 ozs. of basic slag and 2 ozs. of sulphate of potash per square yard now (January), pointing lightly in. We attribute, however, the condition of the Grapes mainly to defective fertilisation. It may be that the stigmas were excessively moist at the time of pollen distribution, which we have known to occur in the case of this usually free setting variety, and especially with vigorous Vines. Pay attention to atmospheric conditions another year during the flowering period, and satisfy yourself that there is a free distribution of the pollen to not over-moist stigmas, and we think you will secure a more uniform set and better standard fruit."]

APPLES.

CANKER ON APPLE TREES.

I OBSERVE that "B.," writing on canker at page 12, mentions that he does not know of an instance where frost cracks have produced canker. I am not quite sure of the date, but I think it was during 1881, when intensely severe hoar frosts prevailed in Middlesex, that immense mischief was done to Apple trees in producing canker, and what I saw in some orchards, especially on rather stiff soils, were then the worst examples of canker I have ever seen anywhere.

Certainly there may be differences of opinion as to what constitutes canker, but whether these frightful cracks and eruptions in bark and wood, in large and small growths alike, were followed by the appearance of the parasite fungus *Nectria ditissima* or not, a worse form of canker than was then manifested I have never seen in any ordinary garden. Lord Suffield, King of the Pippins, and Wellington were three very dissimilar varieties of Apples, that suffered severely. The Kings were so badly hit that some died absolutely. Others recovered in a fashion after several years' pruning and attention. Wellingtons took several years to recover. Suffields became most unshapely. The burstings were not only large and deep, but under the operation of the natural products, of burst cellular tissue, spread rapidly all over the trees.

If this be not canker, may Heaven save our Apple orchards from any similar visitation, for canker is, as I have seen it in private gardens, a far less serious trouble. After all, canker is more a product of starvation than of fungoid production; and all fruit growers should realise that prevention is better than cure.

APPLES AND FROZEN WATER PIPES SPLITTING.

MY critic, H. Richards (page 13), evidently belongs to that adventurous class of persons who readily rush in where angels fear to tread. He displays incapacity to discuss a semi-scientific theory when he holds or propounds the doctrine that pipes containing water are burst by the action of the increased temperature of the water in them when a thaw takes place, and not by the action of frost converting the water into solid ice. Did he ever hear of the conversion of cold water in pipes into warm water bursting them? Did he never hear of the enormous force which water, expanding under the influence of frost, can exercise? Can it be possible that he has no knowledge of a simple elementary fact—viz., that it is the water in the pipes which, under the action of frost, becomes converted into ice, and thus exercises such an immense force on the pipes as to burst them? Surely that little fact in hydraulics is known to every school child.

Does he suggest that when plants in pots standing outdoors in the winter become frozen so hard that the pots crack, that such occurrence is due to the expansion of water in the soil in the pots by a thaw? Again, can he be ignorant of the elementary fact that the great object in exposing wet clays to the action of frost by ridging them is to enable the frost to expand the water contained in the soil, thus splitting open the previously compact soil, and after a thaw not only enabling the water to percolate away, but also to allow air to follow it, and thus to sweeten and dry the soil? Scores of similar illustrations if needed could be furnished to show that water expands materially under the influence of cold, and exercises a potent force that inexperienced people taking effect for cause have wrongly ascribed to thaw.

If any one wants special and very unpleasant experience of the enormously expansive power of ice, let them spend a winter in a ship in the arctic regions, and when they have seen the sides of the ship crushed in by ice or the water expanded by frost they would soon have enough of it.

My little suggestion in relation to the cause of the splitting in stored Apples was a very humble one, one and by no means didactic. It was based on the well understood scientific fact that water in great cold expands, and it was not impossible that sap in Apples might prove to be the same.—A. D.

SPLITTING OF APPLES.

MR. H. RICHARDS (page 13) is rather badly adrift in his endeavour to destroy a theory with regard to the principles of heat and cold. Some years ago I was taught that frost and not thaw was responsible for burst pipes, and practical proofs of the matter can be found in the fact that pipes that hold boiling water with impunity break with melted ice, that cold water is found at the bottom of the pond but ice floats on the service, and in the excellent definition of your print which is due to the fact that "type" is larger when it is cold than when it is hot.

The exact value of "things" as an argument has not apparently entered into "H. Richards'" calculations. Possibly had he laid the fault of the burst pipes to the swelling ice instead of the shrinking water he would be nearer the mark in such cases as he describes, but I am not going into theory manufacture. Let "H. R." fill a bottle with water, wire down the cork, and stand it out in a hard frost. It may be mysterious, but he will find flight more fascinating than approach. It is a good old truism that circumstances alter cases—even of bottles bursting.—RET RAILL.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—JANUARY 9TH.

THE Drill Hall, on this the occasion of the first show of 1900, did not present a particularly attractive appearance. Fruit was practically *non est*. Orchids, however, were fairly numerous, and of a most interesting character. The only exhibit of striking individuality in the floral section was the collection of Primulas from the great Reading firm of Sutton & Sons.

FRUIT.—The duties of the Fruit Committee appeared to be nil, but ultimately Mr. G. Woodward gardener to R. Leigh, Esq., Barham, exhibited dishes of Pears Doyenné d'Alençon and Passe Crasanne, both in splendid condition.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); and Messrs. O. Thomas, Chas. T. Druery, H. B. May, R. Dean, W. Howe, J. F. McLeod, R. B. Lowe, Chas. E. Pearson, Jas. Hudson, E. T. Cook, H. J. Cutbush, Geo. Gordon, Chas. E. Shea, Chas. Blick, Harry Turner, Geo. Paul, D. B. Crane, and J. Fraser.

The chief exhibit in the Hall was a large and attractive group of Primulas from Messrs. Sutton & Sons. The plants had just produced their first flower trusses to perfection; the colours were exceedingly bright and varied, while the dwarf habit of the plants left little to be desired. The single varieties of the *sinensis* section included Brilliant Rose, Sutton's Blue, a Fern-leaved variety; Sutton's Star, a white variety of the stellata section; Snowdrift, Pink Star, Crimson King, a brilliant crimson, possessing a grand habit; Reading Blue, and Rosy Queen, a delicate pink. The double varieties were remarkably fine. Carnation Flaked is a pretty form, white delicately flaked with rose; Improved Double Scarlet, a bright variety with capital foliage; Double Pink, a dwarf variety; and Double White, a free form of good habit. A few plants of The Duchess, a white single variety with a rose centre, very distinct. The exhibit was relieved with numbers of small Ferns and decorative Palms. The same firm also staged Cyclamen Salmon Queen, a pretty variety, and Cyclamen Papilio in a variety of colours (silver Flora medal).

A box of exceedingly bright Rhododendron hybrids was staged by Messrs. Jas. Veitch & Sons, Ltd., Chelsea; the flowers were particularly attractive at this season. The varieties were Princess Beatrice, a rosy fawn; Indian Chief, a bright buff; Delicatum, flesh pink; Cloth of Gold, a pale yellow; Empress, a rosy red; Princess Alexandra, white; Conqueror, red; multicolor Mrs. Heale, a charming white; and multicolor Neptune, a bright red.

Mr. H. J. Jones, Ryecroft Nursery, Lewisham, staged some vases of Mrs. Alfred Tate, the bronze sport from Etoile de Lyon, also a good yellow variety that has sported from Mrs. Alfred Tate; both should be useful for late decorative work. Messrs. W. Wells & Co., Ltd., Earlswood Nurseries, staged baskets of the new late white Chrysanthemum Letrier; the flowers are borne on stiff stalks, while the broad petals possess plenty of substance. It appears to be a good market variety; also a yellow variety, Kakor, bright in colour, with good petals. Messrs. Hugh Low & Co., Bush Hill Park, arranged a table of Cyclamen of the Papilio type.

ORCHID COMMITTEE.—Present: Harry Veitch, Esq. (in the chair); and Messrs. J. O'Brien, De B. Crawshay, H. Little, F. Sander, J. T. Gabriel, H. J. Chapman, W. H. Young, W. H. White, T. W. Bond, H. T. Pitt, J. Colman, J. Douglas, and J. G. Fowler.

Mr. W. H. Young, Orchid grower to Sir F. Wigan, Bart., Clare Lawn, East Sheen, contributed a very bright and attractive group of Orchids, in which Phalænopsis were peculiarly conspicuous. These comprised Sanderiana, Stuartiana, Schilleriana, amabilis, and grandiflora. Other Orchids included were Cypripedium insigne Wigan's var., Loeanum, Rothschildianum, Statterianum, and Marjorie; Pleurothallis Roezli, Zygocolax leopardinum Wigan's var., and Wiganianum; Lælia Gouldiana, and Odontoglossum crispum (silver Flora medal).

A small group of Orchids was shown by R. W. Richards, Esq., The Priory, Usk, Mon. There were two forms of Odontoglossum Rossi, a form of O. crispum with a much branching spike, and Cypripedium insigne, Usk Priory variety (silver Banksian medals). Messrs. B. S. Williams & Son were represented by a collection of Cypripediums, including Sallieri aureum, Loeanum superbum, villosum, insigne Maulei, nitens superbum, discolor, Williamsianum, Pitcherianum Williams' var., rubrum, insigne Fosterianum, insigne albo-marginatum, Fitchianum, Spicerianum, Measuresianum, and a seedling.

Mr. R. B. Lowe, gardener to Earl Brownlow, Ashridge, sent a magnificent plant of Cypripedium Loeanum carrying twenty-six splendidly developed flowers. Messrs. H. Low & Co., Bush Hill Park, staged Cycnches chlorochilon, Cymbidium Traceyanum, Lælia Gouldiana, Odontoglossum crispum, Cypripedium Loeanum giganteum, C. insigne Laura Kimball, a white form of Dendrobium uobile, and one or two others (silver Banksian medal).

Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., Burford Lodge, Dorking, exhibited Calanthes Phoebe, rubro-oculata splendens, limatodes, limatodes rosea, porphyrea, and revertens splendens, Cypripedium fascinatam, Mormodes buccinator Rolfei, M. b. Warscewiczii, Platyclinis uncata, and Lælia anceps Loeana. Mr. E. Shill, gardener to G. W. L. Schofield, Esq., Rawtenstall, sent a couple of Cypripediums; Mr. J. Douglas Lælia Bresies; Mr. Wm. Appleton two Cypripediums; Mr. A. Chapman, gardener to Captain

Holford, Westonbirt, Tetbury, two Cypripediums; Mr. Downes, gardener to J. T. Bennet-Poë, Esq., Cheshunt, Dendrobium spectabile; Messrs. L. Linden, Brussels, Cypripediums and Odontoglossums; Mr. E. Kromer, West Croydon, Brssavola grandiflora; Mr. T. W. Swinburne, Winchcombe, Glos, Lælia Jongheana; and Messrs. Heath & Sons, Cheltenham, Cypripedium Loeanum viridis.

CERTIFICATES AND AWARDS OF MERIT.

Cypripedium Sir Redvers Buller (W. M. Appleton).—This is a cross from C. Smithi and C. insigne. It is a most handsome flower. The immense dorsal sepal has a yellowish green ground, almost obscured by lines of chocolate brown spots; it is margined with white flushed rose. The large pouch is reddish claret. The petals are claret with large brown varnished spots (first-class certificate).

Lælia anceps Loeana (W. H. White).—A pure white variety of fine form. The lip has a slight tinge of colour on the front lobe, and lemon in the throat (award of merit).

Pear Doyenné d'Alençon (G. Woodward).—A well-known variety of proved excellence (award of merit).

Primula sinensis General French (Sutton & Sons, Reading).—A double variety, good in habit and with deep crimson flowers (award of merit).

Primula sinensis (Sutton & Sons).—This well known and excellent strain received an award of merit.

Zygocolax leopardinum Wigan's var. (W. H. Young).—The sepals and petals are green and brown, and the lip is violet (award of merit).

Zygocolax Wiganiana.—This bigeneric hybrid is from Zygopetalum intermedium and Colax jugosus. The sepals and petals are green barred bright brown, and the lip is white, with violet markings (award of merit).

NOTES ON FIGS.

EARLY FORCED TREES IN POTS.—The temperature should now, for trees started in November, be increased to 60° at night, and 65° by day by artificial means, 70° to 75° with sun heat, commencing to ventilate at 70°, closing at 75°, and if the temperature rise 5° to 10° it will be an advantage, provided it is due to sun heat. Avoid, however, a high temperature by artificial means, for it tends to attenuate and weaken the growths, and this is unfavourable to the first and second crops of fruit. The sturdier and shorter-jointed the young shoots can be kept the greater the chances of a satisfactory early crop. Syringe the house and trees twice a day, in the morning and again at closing in bright weather; but when dull sprinkle the floor, pit sides, and walls, as a saturated atmosphere at such times is unfavourable to a sturdy fruitful habit.

As the fermenting material settles firmly about the pots add fresh leaves, bringing them nearer to the rims, taking care that the heat about the pots does not exceed 70° to 75°. Water the trees as required with liquid manure, always before the soil becomes dry. Neglect of water for once only will cause the entire collapse of the first crop. Place some turves about 2 inches thick, grass side downwards, on, round, and over the rims of the pots, extending a couple of inches on the inside and outside, filling the circular dish with rich compost. Sprinkle a little fertiliser on the turves; surface dressing occasionally, and water the turves with liquid manure so as to keep them moist. Stop the growth at the fifth leaf, especially if necessary for inducing a bushy habit, but avoid crowding the trees with growth and foliage that cannot receive plenty of light.

PLANTED-OUT FIG TREES TO RIPEN THE FRUIT IN MAY.—The house containing the planted-out trees for this purpose would be started at the new year, or, if not, there must be no further delay in setting the house to work. The border will probably require repeated waterings to moisten it thoroughly through to the drainage. Avoid, however, making the soil sodden and sour or even very wet, as only moderate moisture is required in the early stages. The surface of the border may then be covered with about 2 inches thickness of turfy loam and decayed manure in equal parts, with one-sixth of old mortar rubbish added. The roots will extend from the collar into this, especially if the mulch be rather thicker there. This will favour surface-rooting, and it will be still further accelerated and growth sustained, both in the wood and fruit, by the application of some approved fertiliser.

The surfaces of the house and trees will require an occasional syringing, but avoid damping the trees in very dull weather, yet maintain a genial condition of the atmosphere by sprinkling the pathways and borders when they become dry. Maintain a night temperature of 50°, 55° from fire heat by day, and from 60° to 65° with sun heat, ventilating freely from that temperature, and losing no opportunity or effecting a change of air daily.—GROWER.

CAMELLIA BUDS FALLING.—In my opinion, the cause of this trouble is often dryness at the roots, the risk of which is greatly lessened by plunging the pots in beds of coal ashes. Since we adopted this plan we have had scarcely a bud drop, though the structure in which the plants are housed is often heated far beyond the requirements of Camellias owing to the presence of other occupants. Were this plan generally adopted as far as practicable, I think we should hear less of this trouble.—S. X.

LIVERPOOL NOTES.

HIGHFIELD, WOOLTON.

WHAT pleasanter time can be spent than one gets in visiting Mr. George Haigh, the practical gardener to Sir W. H. Tate, Bart. Sir William, too, takes the keenest interest in his splendid collection of plants, the houses being of the most approved style. In the matter of attention to his workmen's comforts he stands out prominently, and no better criterion can be arrived at than the excellent opinions of past and present workers on the estate.

Orchids are without doubt splendidly grown, the choice stock (just going out of flower) of some hundred plants of the popular *Cattleya labiata* betokening extra good culture. *Lælia superbiens*, that excellent lasting Orchid, was abundantly flowered, and those with weakly plants

FIG. 6.—EXCRESCENCE ON APPLE TREE ROOT ($\frac{2}{3}$ NATURAL SIZE).

References: *a*, Normal condition of root above the excrescence; *b*, clean state of root below the swelling; *c*, small fibres; *d*, healthy fibrelets on roots; *e*, fibreless roots; *f*, swellings on roots; *g*, fibres at ends of long small roots; *h*, small protuberance on main root; *i*, division in excrescence.

will do well to follow Mr. Haigh's advice and not let such flower, as it only increases the evil. I had sufficient testimony adduced as to the value of such a system by many plants brought under my notice, and, as in everything else, a sound constitution is the mainstay for future flowering.

Oncidium Forbesi, richest of brown shades, was well flowered, with odd plants of *Cattleya Harrisoniae*, delicate in colour at this season, and much appreciated. Fine forms of *Lælia anceps* were open and unfolding. The *Lælia purpurata*, which London travellers know so well, are wonderfully strong in bulb and root, the majority having been divided this season; these with huge spikes of *Oncidium macranthum* wrapped round and round their tall stakes will give me something well worth talking about in a later note.

Odontoglossum vexillarium puzzled Mr. Haigh greatly, but the

difficulty has been thoroughly overcome by finding suitable houses. Cool Orchids find a congenial home in an excavated pit leading from the fernery. A useful stock of Poinsettias, mixed with a capital selection of stove plants, added brightness on a wintry day. A few Chrysanthemums, in which Niveus played a great part, were what were left of a show that has been greatly admired.

And for a close to this short note, may I make one brief allusion to *Masdevallia tovarensis*? Most people see so little in these smaller flowering Orchids against the grandeur of the larger flowers; but I should be quite outside myself did I fail to admire and to add a special word on the charming row of plants I saw in full bloom, the pure white and quaintly beautiful flowers and short dark green leaves being an unqualified success as they stood, or when used for varied floral work.

DOVE PARK, WOOLTON.

I must be excused if I extol the richly flowered Poinsettia somewhat more than is usually the case, but I never saw such excellent results as have been achieved this season by Mr. Carling, the esteemed gardener to Mrs. Cope. There were altogether about one hundred plants in pots from 5 to 7 inches in diameter, the dwarf condition making them all the more valuable. Old and young plants are included, with leaves level to the pots. I am not one to argue the point, when so good a collection is brought together, as to the size of bracts, but a few measured at random gave from 15 to 20 inches, which will give an idea of quality.

I was particular to inquire as to how Mr. Carling kept his plants so dwarf, and he informed me that he never removed them from the frames which they occupy during the summer until the growth is finished and bracts just set, the latter responding freely when placed in heat. He is of opinion that tall ungainly plants are seen through being placed in heat too early.

Bouvardias also are a specialty, and few persons grow them better. Double Bouvardias are not much grown, the grace and elegance of the single varieties, such as *Vreelandi*, *Priory Beauty*, and *President Cleveland*, being of intrinsic value and merit. The fernery is handsome and as fresh as summer, while the large stove furnishes many pleasing features. *Zygopetalum Mackayi* was well flowered; and the outside grounds, varied and extensive, must (I am told) be visited in spring when Daffodils in thousands greet the eye.—R. P. R.

EXCRESCENCE ON APPLE TREE ROOT.

THE growth of the Apple tree root submitted by "C. W., Weybridge," and shown in the illustration, fig. 6, was 5 inches in depth by $4\frac{1}{2}$ inches in diameter and very remarkable. It weighed, free from soil and as figured, 1 lb. 2 ozs. The appearance was that of a series of unnatural protuberances super-imposed, the wart-like prominences being quite clear looking and healthy. The root was normal above, *a*, and below the swelling, *b*, but there was a strange deficiency of fibres. Some of these were small, *c*; others possessed the characteristic fibrelets of the Paradise stock roots, *d*, while some rootlets were fibreless, *e*, and others again had outgrowths on them, *f*. A root issuing from the mass had no fibres except at the extremities of the forked part, *g*. A small protuberance was present on the main root at *h*.

Beyond a sort of division in the excrescence at *i*, there was nothing to indicate the origination of the preternatural growth. It seemed strange if it had arisen from the clean-looking Apple tree root, and not much less so if it was from some other root. The clean-looking Apple tree root had apparently gone through the mass from *a* to *b*. To ascertain this definitely the excrescence was broken up carefully, and the facts now to be referred to demonstrated.

The excrescence was easily broken into four parts, one break transversely at *i*, and each of the divisions thus made vertically in line with the root. It was then seen that the root was forked (fig. 7, *j*) about an inch within the excrescence, and one of the roots thus divided had gone through the lower part of the protuberance, this having grown over and enclosed it. The root was as clean within as without the excrescence, and in no way connected, or even contracted or distorted or deviated from a straight course. A slight scar was present at the point *k*, such as occurs when a fibrelet has been broken off. A side root from it near the fork was a mere stub, and swollen at the extremity, *l*. The root shown on the face of the excrescence in fig. 6 had sprung from the main root at the point *m*, and appeared to have been grown over and partly enclosed, as a too tight ligature round a branch is, by bark and wood.

The other main root ramification or branch, *n*, had come to grief, having been arrested in its growth downward at the point *o*, and in consequence pushed outgrowths of cellular tissue resulting in the excrescence. The only part of woody tissue was that represented in the figure, the remainder of the protuberance being of the character of bark, not unlike that of burrs, hard and knot-like, such as occur on the branches of the Burr-knot Apple tree.

What caused the unnatural protuberance? Unquestionably it had a small beginning, and commenced growing when the root was young, being visible only as a pinhead-like speck on a small root. Some such beginnings are shown in fig. 6, at *f*. Look at the excrescence hundreds of times larger, and notice that its extreme points are precisely similar

to the warts on the small root fibres. Go further with the investigation, and pare off the tip of a protuberance on the large excrescence, and that of a wart on the small root. Compare the tissues, and note that the two have an exactly similar formation. Then take a rather large slice of the unnatural growth, and observe how beautiful the tissue is to the naked eye. A portion of such is shown in fig. 8, at A. It is matchlessly ingrained with gold in silver. The graining in the figure represents the golden colour, and the white the silvery tissue of the Apple tree, while the black marks show the partings between the warts of the protuberance. It is also desirable to note that the gold is always within the silver, and also to observe that the part of the excrescence is joined to the main body by a stem, *p*, just as the preternatural growth itself is affixed on the root of the Apple tree.

A bit of a protuberance enlarged six diameters is figured at B, showing three growing points, *q*, and also a non-protuberancing part, *r*. The cortex (bark) is seen to be dark brown in colour, and more or less granulated, and within appears cellular tissue, indicated by white, is a graining of gold colour represented by wavy lines.

What mean the gold in the silver tissues of the Apple tree root? Excitants of growth—bodies exploiting the host. If so they cannot be symbiotic, that is, leading together a common life for their mutual benefit, for there is no evidence of a reciprocity of services, but of rank parasitism—a drawing away of the growth and nutrition of the Apple tree to serve the ends of the parasite. What is it? Examination of the cells of an active or growing point of a protuberance with the microscope reveals a faintly yellow stain analogous to that of the body found in clubbed cells of a Cabbage plant root. The protuberance cells are very thick-walled, one shown at C, enlarged 260 diameters, showing the protoplasm, *s*, yellowish body, *t*, and nucleus of the Apple, *u*. A bit of the yellowish substance under a lens enlarging 1040 diameters, brings into view the amoeba-like body represented at D, which also shows a nucleus, *v*. It has not a protective wall, but is simply naked protoplasm, and accords with a similar organism found in the cells of protuberances on Alder roots, and named by Möll *Plasmodiophora Alni*.

On an apparently dead portion of the protuberance were found, on the dry part, bodies of a roundish oval form, one shown at E, and on the moist portion the organism represented at F. Possibly the first is a cyst of some species of Myxomycete or slime fungus, and the latter bacteroides, though more likely bacteria. In no instance were either the early or later stages of the bacteroides found in the living cells, nor any bacteria; but in every one of the cells of the protuberance examined was found the gold ever within the silver, and undoubtedly the cause of the remarkable excrescence.—G. ABBEY.

[The soil where the clubbing of the Apple tree roots occurs is very sandy, and appears to be infested with what is known as slime fungus, *Plasmodiophora Brassicae*. Fruit is grown with difficulty, but Scotch Firs thrive in the district. Will the slime fungus attack Apple tree roots or give rise to another form that will? In recent years Potatoes have been infested by a parasite producing preternatural outgrowths from the tubers or underground stems, as figured and described in the *Journal of Horticulture*, December 15th, 1898, page 463. In that case, as in the present one of attack of Apple tree roots, the parasite

produces a dry, not a wet, gangrene, and hence dissimilar in effect to *Plasmodiophora Brassicae*, which causes speedy decay of Cabbages and Turnips. What is best for such land cannot always be obtained. If it was ours we should like to give it a dressing of clay marl, half to a cartload per rod, spread the lumps evenly on the surface, and leave them for the weather to scatter, then dig in, taking small spits so as to mix as much as possible. Failing the marl we should prefer a similar dressing of chalk treated in the same way. Gas lime, 1 cwt. per rod, spread evenly on the surface of vacant land, leaving it there for a month or six weeks and then dig in, would act beneficially. The gas lime must not be used on ground occupied with fruit trees or other vegetation, and it should be fresh from gas works to thoroughly disinfect the land. Stale gas lime will not kill parasites nearly so effectively, though useful in preventing club-root. Basic slag and kainit, about 8 lb. of the former and 2 lb. of the latter per rod, applied now would be good for fruit trees and crops in such soil, as would salt and soot in the spring; but nothing that may be applied can cause such extraordinary protuberances on fruit tree roots to disappear.]

FIG. 7.
PORTION OF ROOT AFTER REMOVING
EXCRESCENCE (NATURAL SIZE).

References: *j*, Fork of root in excrescence; *k*, scar on clean root; *l*, root stub with swollen end; *m*, point of springing of small root shown on face of excrescence; *n*, branch of root bearing excrescence; *o*, point of arrested growth.

FIG. 8.—SECTIONS OF ROOT EXCRESCENCE.

A, Section of a portion of protuberance; *p*, stem of a swelling (natural size); B, portion of excrescence (enlarged 6 diameters); *q*, growing points; *r*, stationary part; C, cell of root protuberance (enlarged 260 diameters); *s*, protoplasm; *t*, yellowish body; *u*, nucleus of Apple; D, amoeba-like body found in apparently living cell (enlarged 1040 diameters); *v*, nucleus of body; E, cyst found in dry portion of tissue; F, bodies existing in moist dead tissues.

produces a dry, not a wet, gangrene, and hence dissimilar in effect to *Plasmodiophora Brassicae*, which causes speedy decay of Cabbages and Turnips. What is best for such land cannot always be obtained. If it was ours we should like to give it a dressing of clay marl, half to a cartload per rod, spread the lumps evenly on the surface, and leave them for the weather to scatter, then dig in, taking small spits so as to mix as much as possible. Failing the marl we should prefer a similar dressing of chalk treated in the same way. Gas lime, 1 cwt. per rod, spread evenly on the surface of vacant land, leaving it there for a month or six weeks and then dig in, would act beneficially. The gas lime must not be used on ground occupied with fruit trees or other vegetation, and it should be fresh from gas works to thoroughly disinfect the land. Stale gas lime will not kill parasites nearly so effectively, though useful in preventing club-root. Basic slag and kainit, about 8 lb. of the former and 2 lb. of the latter per rod, applied now would be good for fruit trees and crops in such soil, as would salt and soot in the spring; but nothing that may be applied can cause such extraordinary protuberances on fruit tree roots to disappear.]

POISON IN LILY OF THE VALLEY.—It seems as though a sprite of vindictive activity is ever whispering into the ear of the investigator. One after another some of our best favoured plants are overhauled and marked dangerous. Everyone will recall the rumpus raised over *Primula obconica*, which has actually resulted in a much lessened cultivation of that charming Primrose. It is true, of course, that the plant did irritate some who handled it, but it is far from generally poisonous, and fully merits more encouragement. And now the latest. A German chemist claims the Lily of the Valley to conceal a most virulent poison—prussic acid—to which indeed he attributes in a large degree the characteristic odour of the flower. Not only is the flower full of poison, but the stalks, too! The attention of this investigator was directed to the Lily of the Valley because his gardener showed all the symptoms of prussic acid poisoning after carrying in his mouth a bunch of the flowers when he had chapped lips. For all the above would not advise anyone to give up growing such a beautiful flower.—(“American Gardening.”)

THE LATE MR. HY. BROOMHEAD, F.R.H.S.

On Sunday, the 30th December, the funeral of Mr. H. Broomhead, of Sheffield, took place at the General Cemetery, where a large number of his friends assembled to pay their last tribute of respect to his memory. The chief mourners were Mrs. Broomhead (widow), Mr. Aldam Broomhead and Mr. John Broomhead (sons), Misses Nora, Kate, and Nellie Broomhead (daughters), Mr. J. Broomhead (brother), Mrs. Clayton (sister), and many personal friends, amongst whom were Mr. H. J. Jones, Lewisham. A large cross of Chrysanthemums (from the Sheffield Chrysanthemum Society) covered the coffin, and wreaths and floral devices were sent by many friends. The whole of the officials of the Sheffield Chrysanthemum Society attended the funeral, also deputations from other societies.

In the death of Mr. Broomhead Sheffield loses one of its best Chrysanthemum growers, and the Sheffield Chrysanthemum Society one of its most liberal supporters. Although he took no active part in municipal or public matters, he was well known as a liberal and active patron of floriculture. His favourite flowers were Chrysanthemums, and he introduced the Japanese section into Sheffield. Every year he obtained new varieties, and the following year every cutting or young plant not required by him was given to his friends. He was also a successful cultivator of Show and Cactus Dahlias.

For upwards of twelve years he held the position of Hon. Sec. to the Sheffield Chrysanthemum Society. In the early period of the Society's history, he for several years presented a sterling silver cup valued at sixteen guineas as a prize for cut blooms, and the following year he gave the same amount in cash in addition to other liberal prizes. On the occasion of the annual exhibitions he gave to each of the scholars of the Girls' and Boys' Charity Schools Oranges and Apples. These scholars, who are regular visitors to all the November shows, will greatly miss his kind liberality.

A few years ago he presented to the Society a large number of valuable books on horticulture and kindred sciences, which he wished to form the nucleus of a substantial library, which has been named in honour of the giver, the Broomhead Library. He was a man with a "big heart," generous in the extreme, but he did not keep a ledger account of his good actions. Everything was done in his quiet unassuming manner. He will be missed by a large circle of friends, but his good deeds and actions will live on and keep his memory green.

In January, 1891, the Society presented him with an illuminated address, a large marble timepiece, and a pair of bronzes, out of respect and regard for his great assistance and generous help in promoting the well-being of the Society.—J. H. S.

THE DAHLIA.

At the last meeting of the Kingston and District Gardeners' Society Mr. Read contributed an interesting paper on the Dahlia. The lecturer thought that this plant is seen at its best when planted in bold masses on extensive lawns, or along the back of large mixed borders; while it may be usefully employed to give colour to shrubberies. Propagation is effected in three ways—by cuttings, division of the roots, and by seeds. To obtain cuttings the old roots must be placed in 6 or 8-inch pots, removing the ends of the tubers to make them fit the pot. Plunge the receptacles in a hotbed standing at 70°, or a bed of soil may be placed on the front of an early viery, and the roots laid on it and covered with soil, leaving the crowns exposed.

Shoots will appear in about ten days, and this is the time to give a thorough watering. When the growths are 3 inches long cut them off and throw them away, as the first shoots are coarse and hollow, and do not make such good plants as the next shoots, which are smaller but harder. Put the cuttings singly in small pots and plunge them in a hotbed at 70°. Shade heavily, but give abundance of air or the cuttings will turn black and decay. When rooted, place the stock in a cooler house, and, after a few days, put them in larger pots, using a compost of two parts of loam, one part of leaf soil, and one part of spent hotbed manure with a little sand. Return the young plants to the greenhouse, and shade for a few days until the roots have entered the new soil.

Old roots to be divided should be started in a warm greenhouse towards the end of March, and when growth has commenced separate into several pieces, each having a young shoot attached. Put these divisions into small pots, cutting large tubers to fit 48's. Keep them in a greenhouse for a time, and gradually harden and plant out at the end of May. If there is no convenience for starting them early, the roots may be planted in the garden in April, and by the time the shoots appear danger from frost will almost be past; but an inverted pot over the plant will make all secure. A rich, moderately heavy soil is the best for Dahlias. Station the plants not less than 3 feet apart, and allow only one shoot to each plant, so as to obviate the thinning of the side branches.

A mulch of manure in the summer helps to conserve moisture, and to afford a stimulant each time water is applied. Liquid manure is very good, but artificials could not be recommended, as they produce rank growth at the expense of flowers. When frost kills the plants, cut down the stem to 15 inches from the ground, lift the roots, remove all soil, and well dry the roots before storing them in a frost-proof shed or cellar; they should be hung up or placed upon shelves. Very small

roots may be stored in dry sand or ashes, but they must not be laid upon the ground, or moisture will arise and favour decay of the roots, and for this reason large roots should never be covered.—J. T. BLENCOWE.

THE YOUNG GARDENERS' DOMAIN.

FREESIAS.

FEW flowers are more popular or useful during the winter and spring months than Freesias. Although their culture is simple, there are probably more failures with them than with any other bulbous plant forced at this season. A number of bulbs may be potted at the end of July, but they must be kept quite cool in a frame and be protected from heavy rains, keeping the lights well tilted to admit plenty of air. Other bulbs should be potted towards the latter end of August and September.

After potting some growers cover the pots with ashes, others leaf soil, but in either case the material must be removed in the course of a week or two, or growth will be seriously weakened. A practice commonly adopted is to cover each pot with an inverted one. It is my belief, however, that the young growths enjoy plenty of light and air from the outset, and each bulb will grow strongly provided it was quite sound. A wet condition of the soil at any stage and too strong heat are both detrimental to the health of the plants. Bulbs in frames must be removed to cool houses as soon as frost appears, and be placed on shelves near the glass in a structure of which the night temperature is 45° to 50°, with abundance of air. Unless desired for a particular date they are best kept in cool houses until the flower spikes appear, then an intermediate one may safely be given. Flowers formed in a higher temperature are of a poor colour, and do not last so long in a cut state.

A light fibrous loam with a mixture of leaf soil, a small part of well decomposed cow manure, and some sharp sand well incorporated will suit them well, allowing proper drainage, and placing eight bulbs in a 5-inch pot. Although copious supplies of water are disastrous in the early stages of growth, frequent applications of liquid manure may be afforded after the flower trusses are formed. Attention must be given to support the spikes and grass to prevent them falling about.—F. W. G.

FRUIT FORCING.

Vines.—*Early Forced in Pots.*—When the bunches are advanced for flowering the atmosphere should be kept rather drier and warmer, and it is a good plan to brush them lightly with a camel's-hair brush when in flower so as to facilitate fertilisation. As soon as the fruit is set, attention should be given to the thinning, commencing as soon as the berries are fairly swelling, removing the smallest first, and allowing sufficient room for the berries left to swell to their full size without wedging or crushing. Water copiously with liquid manure, keeping the evaporation troughs similarly charged. Encourage growth above the fruit, yet only as much as can have full exposure to light. Surface dress the soil with short sweet manure, and when roots are emitted freely from the collar some turves may be placed on. The temperature should range from 65° to 70° at night, 70° to 75° by day, 80° to 85° from sun heat, admitting air from 75°, and closing early, so as to raise it to 85° or 90° with sun heat, damping surfaces at closing time or early in the afternoon.

Early Houses.—These will now require particular care in ventilating, so as not to admit cold draughts of air, which cripple the foliage and produce rust on the berries. Disbud when the best shows for fruit are discernible in the points of the growths, and tie the shoots down before their points touch the glass. In stopping, be guided by the space at command. Remove all superfluous bunches, overcropping being the precursor of deficiency of colour, and some say of shanking in the berries. When the flowers open, maintain a night temperature of 70° to 75° when mild, about 5° less if severe weather prevail, but insure moderate humidity in the atmosphere. Where fermenting materials have been employed in the house, do not allow the heat to decline at this critical stage, but preserve a good heap of Oak, Beech, or Spanish Chestnut leaves and stable litter in the reserve ground, to admit of a supply being obtained as required to maintain the heat of the house with regularity.

Vineries Started at the New Year.—The inside border must be brought into a thoroughly moist condition by repeated waterings or liquid manure at a temperature equal to the mean of the house. A heap of fermenting materials on the floor about 18 inches deep, turning a portion of it daily, is conducive to an even break, and favours speedy growth. Where this cannot be secured sprinkle the floors and borders in the afternoon with liquid manure.

The outside borders should be amply protected against frost, for the roots cannot derive nutriment from a frozen soil. If the roots of the Vines are entirely outside, the border should have a good supply of fermenting material; and if this may not be possible, owing to the scarcity of material, afford dry litter, or Fern or leaves, so as to modify in some measure the chilling tendency of cold rains or snow. Attend to the due protection of the stems, for if these become frozen it is likely the crop will be destroyed. Sprinkle the Vines two or three times a day in bright dry weather, occasionally only when dull. Maintain a night temperature of 50° to 55°, 60° to 65° by day, ventilating freely about 65°, and close at that point.

Late Grapes.—These are best removed to a dry room, where they will keep quite as well or better than if left on the Vines. Keep the temperature of the room at about 45°, examining the bunches occasionally for decayed berries, which must be carefully removed. The Vines should then be pruned after keeping cool for a day or two, dressing the cuts with French polish, patent knotting, or other approved preparation as a safeguard against bleeding; also thoroughly cleanse the house. Admit air freely in favourable weather, striving to give the Vines as long and complete rest as possible. If the borders are unsatisfactory lift the roots of the Vines, clear out the bad soil, rectify the drainage, and relay the roots in fresh sweet compost within 1 foot of the surface, and the fibrous ones not deeper than 3 inches. Where the Vines are planted inside, and have inside and outside borders, the renovation may be accomplished without loss of crop by renewing the former one year, and the latter the year following.

THE KITCHEN GARDEN.

Asparagus.—No vegetable is more easily forced than Asparagus. The genial moist heat of a hotbed formed of leaves and manure answers much better for forcing than the dry heat of hot-water pipes; but if hot-water pipes are available the heat should be turned on during frosty weather. The roots of lifted plants must not be unduly exposed to drying winds. When preparing for forcing cover a mild hotbed with a thin layer of rich, moist soil, on this packing the Asparagus plants closely, spreading the roots out and covering with 3 inches of fine rich soil. Keep the soil constantly moist. Form and fill successional beds according to requirements.

Kidney Beans.—From this time onward Kidney Beans in pots pay better for forcing than earlier in the winter. To be successful with them the essentials are abundance of room, heat, light, and moisture. From twenty-five to fifty 9-inch pots, each containing about six plants, form a good stock, a considerable amount of bench or shelf room being necessarily devoted to them. No advantage is derived by allowing room for top-dressings of rich compost, the plants failing to root into this, and the simpler plan of filling up the pots at the outset really answers better. Sion House, Ne Plus Ultra, or other well-tried newer varieties and new seed are recommended for forcing. Water sparingly at first; but when the plants have formed abundance of roots they require water and liquid manure, with frequent syringing to keep down red spider.

Carrots and Radishes.—The mild autumn was in favour of a late growth of Carrots, and, in addition to what resulted from sowing late, many unthinned rows have made extraordinary progress, an abundance of tender young roots being available. These keep best in the ground, but a covering of straw litter should be afforded. A supply of young roots ought, where possible, to be maintained with the aid of hotbeds and frames. Leaves, mixed with previously fermented stable manure, are suitable, as only a mild heat is needed. Form rather solid beds facing south, and not less than 3 feet deep at this early date; place shallow frames on these, inside of which more of the shorter heating material should be placed, or sufficient to raise a depth of 6 inches of light sandy soil close to the glass. Cover with lights and mats or litter, and when the soil is well warmed through, and there are no signs of overheating, sow seed thinly in shallow drills 8 inches apart. Between these form other drills for Radishes of good forcing types. Cover all the seeds with a little sifted soil. Close the frame, placing mats or litter, or both if severe frost is anticipated, over the lights. If much vapour collects in the frame push down the lights slightly.

Onions.—The exhibitor's plan of raising a number of Onion plants under glass and planting out in April is equally desirable where Onions are required for ordinary purposes. Especially is this plan of raising under glass and planting out desirable in cases where the Onion maggot is most destructive, strong early plants to a certain extent proving impervious to attacks. Sow seeds at once in boxes of fine loam, leaf soil, and Mushroom-bed refuse. Place in gentle heat of about 60° to germinate, transferring to shelves when the seedlings are well up.

Potatoes.—Quick if comparatively light crops may be had by pot culture. Short-topped early varieties are suitable for forcing, and these ought to have their first or primary sprout attached. One strong tuber is enough for each 8-inch pot for shelves, while three may be placed in each 11-inch or large pot, arranging these on light borders in houses where gentle forcing is being carried on. When filling the pots with a mixture of loam and Mushroom-bed refuse allow room for a top-dressing of soil after the sprouts are showing above the rim level. Give enough water to keep the soil uniformly moist. Time will be gained by first starting tubers that are to be forced in pits or frames in gentle heat and a moist atmosphere.

THE BEE-KEEPER.

CRYSTALLISATION OF HONEY.

The crystallisation of honey is only imperfectly understood. How is it that honey obtained one season will granulate much more readily than that produced say the previous or following year? That such is the case the majority of bee-keepers who work for run honey will have observed, although the honey has been obtained in the same district, and, so far as one can judge, from the same variety of flowers. We are inclined to think fine weather and a high temperature are the chief factors. But this will not wholly account for it. One year in our experience stands out very conspicuously in this respect—namely, the Jubilee year 1887. The weather during the honey flow in that memorable bee-keepers' year was perfect from a bee-keepers' point of view. The days were fine and bright, and the nights warm. The pastures were a mass of white Clover, there being sufficient moisture in the land to prevent the plants suffering from drought. The result was a rich harvest of honey of the best quality.

During the last week of June we extracted the honey from the supers of all our hives that were being worked for run honey. Being short of storage room we commenced bottling it the following day. We were surprised to find it had already that clouded appearance which usually precedes granulation. Within a fortnight perfect crystallisation had taken place. Since that time we have obtained honey under a variety of circumstances. Similar weather has prevailed for a short time, but granulation has not taken place so quickly.

The nearest approach to similar weather was that prevailing in the neighbourhood of our apiary early in July last year; the honey flow was at its height. Owing to the drought there was not such an abundance of white Clover, and the Limes were just bursting into bloom. The stocks were in similar condition to those mentioned above. We therefore prepared for similar results to those obtained in 1887. Although we examined our honey almost daily we found that crystallisation did not take place till quite late in the autumn, a very fine sample of honey we had on hand being quite liquid and clear at the end of November. Probably the honey obtained from the Limes would have this effect on it. Honey collected in dull and rainy seasons does not usually granulate in its early stages.

HONEY FOR MARKET.

How should run honey be placed on the market? Should it be clear and in similar condition to what it is when it comes from the hive? We are induced to ask this question, as we have found in times past that dealers preferred to have it clear and not in its granulated form, as their customers were under the impression when offered in the latter condition that it was adulterated with flour. How the latter ingredient could be mixed with the genuine honey we are unable to say. The above fact has been brought to our notice not once but many times. As granulation is one of the proofs of genuine honey we took some trouble to disprove this fallacy. We laid stress on the latter fact, and explained how easily honey may be made clear again by placing the jar containing it in hot water. So that there should be no misunderstanding on this point, the above facts are printed on our own labels, which are attached to all our jars of run honey.

What has been the result? Dealers now often inquire why the honey is not granulated, as their customers prefer it in that condition. This is a point gained, as it is a well-known fact that much of the foreign stuff sold under the name of honey had never been near a bee, or in a bee hive, and more often than otherwise is in a clear state. Thus when granulated honey in a pure state was placed on the market it was looked on with suspicion.

Honey in sections that has not been marketed should be kept in a warm dry place. They have not kept as well as usual this winter, judging from the samples to be seen in some of the shops, which were quite spoiled owing to the moisture dripping through the whole surface of the comb.—AN ENGLISH BEE-KEEPER.

BEEES IN STRAW SKEPS.

I HAVE five or six weak straw skeps and a dozen bar-framed hives. Is it possible to drive these five weak stocks into one hive, and if so when must the work be done?—S. S. W.

[Any attempt at driving the bees from straw skeps at this season would only end in disaster. Are the stocks really short of stores? It is possible to form a fairly correct opinion as to the amount of stores contained in each skep by weighing them. "S. S. W." does not mention the size of the skeps. These are made in various sizes, the majority of them being much too small for the object in view. If the skeps are 14 inches or upwards in diameter, and are filled with combs, they should weigh at this date 20 lbs., and will have sufficient stores for another three months. If the skeps are small an allowance may be made.

It is surprising the small amount of stores a weak colony of bees

will consume when wintered in a straw skep. We once experimented with a late cast which had barely half filled the skep with combs. In October there were only three combs of sealed stores the size of one's hand. Still they wintered successfully, and were not fed till the following April. They were then fed with a small amount of thin syrup daily, and increased at a rapid rate. A strong swarm came from this stock early in June, and was placed in a frame hive, fully drawn out combs being used. The weather being favourable a large surplus was stored. We mention these facts to show what an apparently weak stock in a straw skep, with careful management, will sometimes do.

If the stocks are short of stores a plentiful supply of soft candy should be given them without delay by pressing it into the feed hole at the top of the skep; some warm covering should be placed over it to prevent an escape of heat from the hive. During last autumn we examined many skeps of bees, and invariably found them well supplied with stores owing to the fine weather that prevailed in late summer. Probably the skeps mentioned above were robbed of their summer stores. When the weather is warm, say about the middle of May, the bees may be driven. We should, however, prefer transferring them to frame hives. A better plan would be to stimulate them by feeding with thin syrup as mentioned above; they would then swarm early. When the young queen, which would afterwards be reared in the skep, has become fertilised, the bees may be driven and united to the swarm after the removal of the old queen has taken place, the stocks would then be all headed by young fertile queens.—AN ENGLISH BEE-KEEPER.]

All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Stocks for Apple Trees (*Amateur Apple Grower*).—The statement you quote is not correct. The Crab or wild Apple is *Pyrus malus*, a small tree, native of Britain and Europe generally. It is raised from seed, but most of the so-called Crab stocks are raised from Apple seeds obtained from the cider mills. The stock from the Apple pips we prefer to the Crab, because as a rule it produces more fibrous roots and is quite as hardy. For dwarf trees we prefer the broad-leaved English Paradise, which is freer and hardier than the French Paradise. Paradise stocks, being surface rooting, are better for shallow soils than Crab stocks, and by feeding the trees and mulching of the former they afford profitable crops of fruit. Our observations are based on practice, which is better than theory.

Treatment of Deutzias (*F. G.*).—As the young leaves turn brown at the ends, the soil has probably become soddened and sour through the constant watering. In that case it would be advisable to allow the soil to become rather dry, then turn the plant out of the pot, remove most of the old soil, and give such size of pot as will hold the roots comfortably, Deutzias being better under rather than over-potted. Provide proper drainage, and employ a compost of good turfy loam, enriched with a fourth of well decomposed cow manure, or one-third of leaf mould, with the addition of one-sixth of sharp sand. Pot rather firmly, and keep the plant in the greenhouse in the lightest position at command until the weather becomes sufficiently genial for placing it outdoors. A temperature of 45° to 50° is quite sufficient for the development of the young growths, air being given at 50°, then the advance to 65° or 70° on bright days will not do any harm, especially with ample ventilation.

Repotting Marantas (*G. H. F.*).—This operation should be carried out during the present month, so that they will have a chance of establishing themselves again before the sun has much power. If they are left till about the middle or end of the following month the sun often proves too strong for them, and they flag severely. These plants will do in the same pots for years provided the drainage is good and the soil about the roots in a sweet condition; but the liberal supplies of water needed during the growing season soon render the soil unfit for them. They unquestionably thrive best when they are repotted annually. When turned out of their pots and the drainage removed the old soil should be worked from amongst the roots by washing it out in a tank of tepid water. This necessitates the plants being allowed to drain for some hours before they can be repotted. Many of the varieties do well in a compost of fibrous loam, one-seventh of manure, charcoal broken according to the size of the plants and pots, with an addition of coarse sand. Others do better in rough peat, the fibrous portion of loam only, and charcoal in lumps. After potting plunge the plants where a night temperature of 65° can be maintained, syringe them freely, but water with great care until the roots are active. The pots should be liberally drained.

Marie Louise Violets (*E. L. M.*).—The flower buds are blanched or "greened," as usually occurs during too cold and too wet or foggy weather for their proper development. The only preventive is a more genial atmosphere, which can hardly be looked for at this season. To grow Violets with certainty of success at this time of year it is necessary to have means of affording heat, maintaining a temperature of 45° to 50°, accompanied with some air, unless very cold and when fogs prevail outdoors. Except when the weather is unusually mild there is always the danger of having the blooms in the condition yours present from November to February, the flowers being good in the early autumn and then again in the early spring. Such has been our experience, and we have grown many thousands of plants in frames. The soil is excellent, but we use rather more leaf soil—in fact, we find the Neapolitan varieties revel in it. It is used alone for potting crowns in the late summer, and the plants do splendidly well up to the light in a greenhouse with a temperature of 45° to 50°. We do not see what you can do under the circumstances, as the treatment is correct, the only fault being the weather, which will take a turn for the better in due course, and the flowers will develop properly. We failed to discover the small red specks on the under side of the leaves, which had got strewn with soil. Possibly they may have been red spider.

Unhealthy Lapagerias (*W. R. T. P.*).—There are two main reasons why these plants are often in an unsatisfactory state in pots:—1, Close, soil not sufficiently drained, and hence sour. 2, Pots so densely crowded with roots that the plants do not receive adequate support. Lapagerias usually grow best planted out in a bed at least 18 inches deep, the bottom 6 inches being of drainage, broken clinkers and charcoal being excellent, the remainder springy turfy peat and loam, twice the quantity of the former, with a liberal admixture of charcoal, the whole to be pressed down as firmly as the turfy nature of the compost permits. A bed thus prepared can scarcely be made sour, due provision being made for the free exit of water from the drainage, and when the soil is permeated with roots it is not easy to give too much water; until then water must be given more sparingly, yet the soil should never get anything like dry. If you prefer growing the plant in a pot, prepare the soil similarly. In the event of the plants not having rooted freely, it will be advisable to remove a good part of the old soil, which will be sour, and give fresh as suggested, thinning out and shortening wiry growths to the best buds you can find, syringing the plant twice or thrice a day according to the weather, to prevent excessive evaporation from the leaves, and so assist the emission of fresh healthy roots, which alone can invigorate the plants. We know of Lapagerias that grow luxuriantly and flower profusely on the north side of greenhouses.

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. The practice of pinning numbers to the eyes of the fruits tends to destroy one of the most characteristic features and increases the difficulty of identification. When Plums are sent to be named young wood of the trees should accompany them. Leaves of the trees are necessary with Peaches and Nectarines, with information as to whether the flowers are large or small.

(A. B. C.).—Dutch Mignonne. (A. P.).—1, Gloria Mundi; 2, Newton Wonder; 3, Cox's Orange Pippin; 4, New Hawthornden. (A. D.).—Winter Hawthornden. (J. T. B.).—1 Ribston Pippin; 2, Northern Greening; 3, Blenheim Pippin; 4, Alfriston; 5, Warner's King; 6, Bramley's Seedling.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (F. H.).—1, Phoenix dactylifera; 2, Kentia Canterburyana; 3, Raphis flabelliformis; 4, Cocos Weddelliana; 5, Kentia Belmoreana. (P. P. J.).—1, Ophiopogon jaburan variegatum; 2, Selaginella Kraussiana. (S. E. D.).—1, Oncidium tigrinum; 2, O. Forbesi.

VINTON'S ALMANAC.*

WE noticed some little time ago an excellent almanac that came under our notice, the "Live Stock Journal." It was full of improving and interesting matter, well got up, clear type, and altogether well worth the 1s., its advertised cost. Now we make the acquaintance of another equally good, though not quite so large, which is purchasable for the small sum of 6d. How it is done at the money is a puzzle; even if the writers gave their services gratis, there must be a great outlay, so we think that the circulation must be immense, or the thing could never "go" at all.

All of us, young and old, turn first to pictures, and here we find a most capital one of that well-known and popular agriculturist H.R.H. of Wales. He will not think we take a liberty when we say he looks like a typical English squire, who delights in the home farm, and is more than proud of the honours won by his exhibits in the show yard. H.R.H. has always been closely identified with the farming interest, and has shown himself always ready to support in any and every way he could this important industry. Who can calculate the long and tiring days he has spent at shows since the time he was first taken as a lad by his noble father? Hot or cold, rain or fair weather, the Prince is never absent. Not only has he thus encouraged the executive of the shows, but he has given an opportunity to many thousands of his subjects to see their future king. His Royal mother and he well earned their right to the medals, rosettes, and ribbons that have gone respectively to Windsor and Sandringham.

There is another portrait of a younger man, the scion of an old ducal house, with whose name we associate Holker Shorthorns and Shires. As the country people would say, Victor Cavendish decidedly "favours" in appearance the present head of the great race of Devonshire.

Then we find some fine live stock, the majestic Shorthorn; the elegant fairy-like Jersey Busiest Harold, the king of the Shires; the grandly formed Suffolk Pearl, Sir Walter's Danish Duke, a perfect gentleman; and the smart hackney Confident George. There are only two sheep depicted—a Southdown ram from the Prince's, and a Shropshire ram owned by Mrs. Barrs.

The papers on the different subjects are all good, and it seems invidious to pick out one. Of course we each have a natural bias, and we must allow that Professor Wrightson on Barley appeals to most of us. J. P. Sheldon will interest those who have at all studied the question of permanent pastures; he has much of value to say on the subject.

* "Gazette" Office, Ludgate Circus.

W. E. Bear tells what Parliament has done and left undone in the past session for the farmer. We have not got a great deal out of our legislators; we suppose they prefer that we work out our own salvation. This margarine question is still untouched, and though the Bill to prevent the adulteration of foods is good in itself, it by no means covers the ground it should. Poor old Ireland gets a Bill which is intended to encourage agriculture and technical education.

We see that 10,000 of the clergy will get relief to the amount of £87,000 per annum by the working of the Tithe Rent Charge (Rates) Act, and only those who know something of the poverty and difficulty of the poor parsons who derive their incomes from land can tell what this means. It will be but a trifle apiece, but it will ease the strain a little. There is a measure which is very desirable. Up to now Parish Councillors were elected annually; now each member is to sit for three years. This will do away with a good deal of silly ferment, that was quite unnecessary as an annual.

And so separated milk has had its day. "Machine skimmed" is to be the new definition. Professor Lloyd tells us that to some minds "separated" conveyed the idea of something super-excellent; and if that is the case it is as well to clear up the matter. "Machine skimmed" sounds awkward; but we are old-fashioned. There is a future for it, the Professor says, if only it be Pasteurised before sale; it is a wholesome, excellent article of diet, and invaluable for the preservation of infant life.

The management of feeding cattle is ably treated of by T. P. F. Bell. He goes into the question thoroughly, giving sensible ideas as to rations, laying great stress on cleanliness—i.e., cleanliness of body, freedom from harbles and lice, cleanliness in byres and feeding troughs, stalls, and watering places. No doubt we should hear far less of tuberculosis if all sheds and loose boxes were constantly whitewashed, and so constructed that sun and air could have free access. Mr. Bell is of the same opinion as ourselves on one matter in particular, and that is that there should be as few changes in the attendants as possible. All stock have their peculiarities, and a new man is some time before he gets to know all about a herd; and, in the meantime, his very presence disquiets them.

"The Milk Trade" is not altogether very pleasant reading to the tenant farmer. He knows full well what a business it is to keep up his proper quantity of milk, and then to find he rarely can make his way, though the town folks are paying up well. P. McConnell says there is no investment better than a good milk walk. The retail vendor gets the cream (we do not mean a pun), and there is nothing for the farmer but co-operation.

The home harvest in two periods, 1872-76, 1892-96, is full of facts and figures. Unlawful poisoning shows up curious points of law, and "centipedes and millipedes" make us feel quite creepy.

Every lover of vegetables should read Mr. Glenny on salads. If only folks would consult their stomachs and purses by eating more "green meat," how much better they would be. But English people adore solid meats. The poultry paper might, with advantage, have been longer.

The book is not yet exhausted. All sorts of official information, lists of societies and agricultural training depôts, dairy schools, fairs, markets, and tables, that we shall only be too glad to have handy for reference, and all within the covers of a sixpenny book.

WORK ON THE HOME FARM.

The frost has been of short duration, and though one night was rather severe, we hope that the Turnips will not be much the worse for it. A steady rain has well washed the roads, and done the Wheat nearly as much good as a rolling. Wheat looks well and is forward, but has never had too solid a seed bed to grow in. There must be danger from wireworm as spring approaches, unless the roll be used whenever practicable.

It is a good plan to take the roll into the Wheat field soon after Christmas, and being on the spot ready for use many opportunities may be found of using it, if only for a few hours. Suppose the horses are ploughing or harrowing in a neighbouring field, a brisk wind springs up, the surface quickly becomes dry enough for the roll; the master or foreman seeing the opportunity diverts a pair of horses to

the roll, and half a day's work is done, which must have been left altogether, or done at a less useful period.

The poultry raiser who wishes to realise good prices must have eggs already in a state of incubation. As hens are perverse creatures, and will not sit or lay simply when they are ordered, true enterprise suggests the use of the incubator. We have tried one very successfully, and are sure that it amply paid for the outlay. There are many useful types. Ours was a Hearson; and others, we are told, are equally good, but we have not tried them.

With open weather we shall commence to cross-cut the fallows. Should frost again intervene, the land will be all the better for having been moved in the interim, as it will be more open to frost influence. Strong land, however, must not be ploughed wet, or the benefit of the previous frost will have been lost. One of the chief attractions of light free-working soil to the farmer is the possibility of keeping horses at work upon it; when on strong land they must perforce remain idle.

The labour difficulty gets worse day by day, and we hear of a land agent backing up tenants in appealing to their landlord for rent reduction, and chiefly on the ground of the vastly increased labour bill. Unless there is a radical change, and that soon, further large tracts of arable land will have to be seeded down.

FIELD EXPERIMENTS WITH MANURES.

PROFESSOR J. R. Campbell, of the Yorkshire College, writing in this month's "Land Magazine," warns farmers against placing too much reliance upon the results of field experiments in the manuring of crops. For ten years past various agricultural bodies have been conducting such experiments, and the principal lesson they seem to have taught is that the whole question must for a long time remain in an experimental stage. Variations in the soil and changes in the weather make it necessary, if experiments are to be relied upon as a guide for practice, that they should be spread over a wide area and continued for a long series of years. At present, therefore, Professor Campbell thinks it useless to tabulate the results even of those experiments which seem the most conclusive; he prefers to state some of the general principles these experiments have established.

The first is the very elementary discovery that farmyard manure is the best. The farmer who uses it "can make no mistake." It contains nitrogen, phosphoric acid, and potash, and these constituents must be blended in any artificial manure that is to take the place of the natural product. No experiments were needed to establish this fact. But the question of how manure should be used is one upon which farmers are not agreed. Practice varies in different counties. Professor Campbell lays it down as an axiom that the system of manuring the root crop heavily and using no manures for the rest of the rotation is not so profitable as that of distributing the manures over the rotation. The contrary practice is sometimes recommended, but the Professor's advice is the fruit of study and experience, and to farmers he says urgently, "In all-round manuring you know you are safe. Leave these problems to experts. For yourselves, run no risks."

In the second place Professor Campbell recommends more frequent use of artificial manures to the grain crop. It is indirectly profitable, even with oats at 2s. a bushel; it produces a large crop, which loosens the soil and keeps down weeds, and a plentiful yield of straw increases next year's stock of manure. In many counties this system is extending, but Professor Campbell urges more care in the selection of the manures. "No result," he says, "has been more striking than the certainty with which an increase in the yield of the corn or grass crops has been secured by the use of nitrogenous manures, particularly quick-acting manures, such as nitrate of soda or sulphate of ammonia." It is a mistake to suppose that these are exhausting to the soil; on the contrary, they increase its fertility. Artificial mixtures often contain excessive quantities of phosphoric acid and are harmful, but plenty of nitrogen produces bulk, and bulk will produce a fine manure. Finally, experiments conducted by Professor Campbell in Yorkshire and in Scotland show that for arable crops a quick-acting manure, and for pasture a more lasting one, are best.—("Yorkshire Post.")

POULTRY AND EGGS—Almost everybody who has a little spare space, and a good many who really have not, manage to keep a few hens, and oh, how anxiously they look for a new-laid egg or two every morning now; and the look is apt mostly to be in vain. Two things are too often overlooked in regard to feeding, and that is not to supply plenty of green uncooked vegetables and enough grit. Without these neither health nor free laying need be expected. The green vegetables may consist of turnip tops, cabbage leaves, and such like, and the grit be obtained by breaking up all old crocks and glass bottles on the premises into bits not larger than grains of wheat. As a rule the birds are really overcrowded with corn and meal. Of course, it is desirable that a wide out-run be given; then the birds look after both green vegetable food and grit, but they cannot find it in the small homes many of them have to live in. Dampness and draughts, too, in any form are bad for fowls. They stop laying, bring about disease, and hinder free growth in the young birds.—("Rural World.")

BARR'S SEED GUIDE NOW READY (FREE).

BARR'S SEEDS

OF FINEST SELECTED STRAINS
AND TESTED GROWTH

THE BEST SEEDS IN THE WORLD for securing a supply of Vegetables "the year round," and for keeping the Flower Garden always gay, and with abundance of Flowers to cut for vases and bouquets; also Seeds of Plants for Greenhouse decoration summer and winter.

BARR'S SEED GUIDE contains a select List of the best Vegetables and the most beautiful Flowers for Garden and Greenhouse. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors, SENT FREE ON APPLICATION.

BARR'S 21/- COLLECTION OF VEGETABLE SEEDS contains a liberal assortment of the following useful Vegetables: Beans (Broad and French Beans), Beet, Borecole, Broccoli, Brussels Sprouts, Cabbage, Capsicum, Carrot, Cauliflower, Celery, Colewort, Corn Salad, Cucumber, Cress, Endive, Herbs, Leek, Lettuce, Melon, Mustard, Onions, Parsley, Parsnips, Peas, Radish, Salsify, Savoy Cabbage, Scorzoneria, Spinach, Tomato, Turnip, and Vegetable Marrow.

OTHER COLLECTIONS OF BARR'S VEGETABLE SEEDS, 5/6, 7/6, 12/6, 42/-, 63/-, and 105/-.

These Collections sent by carriage paid on receipt of remittance. Full particulars on application.

BARR'S CHOICE FLOWER SEEDS.—The "Seed Guide" contains a Select List of all the most beautiful Annuals and Perennials. Special Collections for all purposes, and many Sterling Novelties. All Seeds sent Carriage Paid on receipt of remittance.

BARR & SONS,
12 & 13, King Street, Covent Garden, London.
Nurseries: LONG DITTON, SURREY

ECKFORD'S SPECIALITIES

ONLY GENUINE DIRECT FROM WEM
AWARDED 46 GOLD & SILVER MEDALS

SWEET PEAS!

The BIGGEST SUCCESS of all is ECKFORD'S GIANT SWEET PEAS. The PURITY and STAMINA of these Home Grown Stocks are so conserved by SPECIAL METHODS of CULTURE that the seeds are PHENOMENAL for UNRIVALLED STRENGTH and VITALITY, and with proper cultivation, give the HIGHEST POSSIBLE MAXIMA of results! Prizes offered in 1900 alone exceed £40! Collections from 1/6 upwards. (See particulars in Catalogue.)

See beautiful plate of SWEET PEAS NOVELTIES for 1900, sent gratis with each Catalogue.

CULINARY PEAS!

ECKFORD'S CULINARY PEAS are positively UNRIVALLED by any on the Market for FLAVOUR and CROPPING CAPACITY! ENORMOUS YIELDS under favourable conditions. Collections for 5 months continuous supply (See page 2 Catalogue.)

PURE VEGETABLE SEEDS!

Results from ALL QUARTERS prove that ECKFORD'S SEED, for PURITY, VIGOUR, and YIELD, are the CHEAPEST and BEST ever offered to the public! Collection for 12 months supply, 12/6, 21/-, 42/-, 63/-, 105/-, all carriage paid. Other Collections, 2/9, 5/-, 7/6, post free.

CINERARIA (SILVER MEDAL STRAIN). Giant Flowers, splendid habit, unequalled! PRIMULA SINENSIS. Unique Novelties and Grand Collection of named varieties PANSY. World-famed strain of FANCY, SHOW, PEACOCK, and FLAKED VARIETIES! VERBENA. RENOWNED RACE of EXCEPTIONAL MERIT!

Don't buy till you have seen it! ILLUSTRATED Catalogue & Cultural Notes POST FREE! If you love Gardening send for one!

SEED CROWER, WEM, SHROPSHIRE.

ORCHIDS.—ORCHIDS.

QUANTITY IMMENSE.

By Special Appointment to H.R.H. the Prince of Wales. Inspection of our New Range of Houses IS CORDIALLY INVITED BY

HUGH LOW & CO., BUSH HILL PARK, MIDDLESEX.

WEST'S PATENT GARDEN SPECIALITIES.

WEST'S PATENT Vapourising Fumigator

Best and Cheapest, for being made of brass and zinc will last for years. The stove only requires a little spirit to saturate the asbestos, so may be used thousands of times without wick or further trouble than filling it. Price 6d. complete to vaporise up to 2500 cubic ft.

"WEST'S EXTRACT OF NICOTINE" is guaranteed pure Nicotine and is even cheaper than the compounds that are only chemical substitutes for Nicotine (compare prices), 7d. per air-tight sealed bottle of 1000 cubic ft.

"SUNPROOF" SHADING in 6d. lb. tins ready for use, to be mixed with cold water. Guaranteed to be perfect in all respects and the cheapest shading that can be made.

For particulars of West's patent "Ivorine" Plant Labels, Soft Metal Tree Fasteners, S.M. Clips, Wall Nails, Plant Stake Grips, Plant Pot Cocks, Insecticides, Fertilisers, Canes, Sticks, and ALL GARDEN SUNDRIES of every description see Illustrated Catalogue, post free.

Samples free, postage for samples and goods extra. All goods made on the premises by C. E. West, so send direct to the Manufacturers.

Gratis, "Orchid Culture," 3rd Edition, postage 2d. Gives full particulars of the cultivation of Orchids.

THE LEEDS ORCHID COMPANY, ROUNDHAY, LEEDS

SEEDS AND SEEDLINGS.

THE near arrival of that period of the year when, with lengthening days and renewal of heat, nature begins another season's growth, reminds one that it is possible not only to aid in that work but also, unfortunately, to hinder it. It would be a gross libel on gardeners, and, indeed, on all who love a garden, to say they would knowingly do anything of the latter kind, or, on the other hand, omit help where necessary. But, allowing the truth of that, it cannot be gainsaid that all of us are apt to err frequently through want of definite knowledge and not seldom through excess of zeal. The practice of sowing seeds too thickly has been so often condemned as in every respect an evil that it may for the present be passed over without comment.

Closely allied in its bad effects, though of course not so pronounced, and, indeed, generally passing without notice, is the system of allowing seedlings to remain too long in the seed bed—in which expression pots and boxes are included—before transplanting, which, I think, is a practice than which none is more general. "Too long" is somewhat indefinite, and few will plead guilty to any such thing. Nevertheless, I am convinced the instances that occur of plants being hindered in growth by this one cause is beyond computation. The beneficial effect of transplanting seedlings while yet very small can, indeed, be comprehended fully only by experiment, when without a doubt those that are left till they have gained so-called "strength" previous to transplanting will in many instances appear for a time the better stock, but ultimately they will be left behind. Seedlings which are minute in an early stage of existence are by the inexperienced commonly allowed to remain in the seed bed far too long. Common examples that may be mentioned are Begonias, Gloxinias, Calceolarias, Pentstemons, Lobelias, Francoas, and Salpiglossis, all of which should be transplanted when yet the tiniest mites. How, remarkably, too, is the future of a Tomato plant affected by its treatment as an infant seedling, not only in earliness but also in crop.

One of the very old writers attributes the value of transplanting to be derived from the roots being broken in the process with subsequent access of new ones to lay hold on the fresh soil. The question is one worth pondering. We never dream of doubting the value of transplanting certain crops—*e.g.*, the Brassicæ, and those who cultivate Parsley by transplanting from seed beds know that it is in every respect superior to that not so treated. In the same way, transplanted early, Peas and French Beans are superior to those sown where they crop. But to return to the subject more immediately under review.

Not the least remarkable examples of the beneficial effects resulting from early transplanting are provided by monocotyledonous plants. In the case of *Amaryllis* and *Gladiolus* it is possible to lose or gain a twelvemonth in the period of flowering from this cause alone. If for example the seeds of the last named are sown in pots or in boxes in early spring and started in a little heat, but allowed to remain during the season without transplanting, treat them as carefully as one may, the corms will be small at its end. On the other hand, if the seedlings are transplanted, say in May, into the open garden, in a few weeks the little fellows will exhibit their satisfaction, and the corms when lifted show the value of the practice still more plainly. Or one might refer to any common *Dracæna*, the seedlings of which if transplanted at an early stage and duly potted, all through retain the lead of those left a little longer in the seed pan.

The practice of transplanting Onions from boxes affords another incontrovertible proof. Smaller plants placed out early certainly out-grow stronger ones allowed to remain longer in the seed boxes. Leeks provide an object lesson equally striking, and those who allow seedlings of this highly estimable vegetable to remain, for whatever reason, in the seed lines after the plants are at a proper stage to transplant, do so at a great loss of weight in the crop. Celery is a valuable crop that is frequently prejudiced solely by leaving the seedlings too long without transplanting, and perhaps more often still by allowing the transplanted stock to get too large previous to removing to the trenches.

Without educing more examples, note may be made of the value of early transplanting for another reason. The occurrence is by no means infrequent that seedlings raised under glass, and particularly when the subjects are somewhat hardy and a degree of artificial heat has been used, that great loss accrues from damping. One method of checking this is to remove to a cooler temperature, or to lower it in the structure where the plants are affected. But an infallible means of staying this plague is to transplant without any delay those seedlings which have not been attacked, and the better plan still to prick out the seedlings at so early a stage of growth that this troublesome visitation is never made.

In strict connection with what has been already indicated should be the lines of treating young seedlings, is the question of the most suitable times to sow. In not a few cases, and more particularly so with plants that are prepared for decorating the summer garden, the seeds are sown at a date that is earlier than is necessary, and the result is delay in effect through check to growth when young. There are plants, such as *Pentstemons*, *Lobelias*, and *Begonias*, which must be sown early in the year to secure a strong floriferous plant, but with rapid growing kinds, such as *Asters*, *Marigolds*, and *Sunflowers*, there is no gain from sowing early.—B.

THE WILD GARDEN.

CAN we contemplate anything that will give more effectiveness and tone to a garden, or that will produce so much beauty and pleasure, as is likely to arise from the naturalisation of such plants as will take care of themselves when planted near to the margins of shrubberies, or on lawns where the ground is never dug? We take it for granted that anyone proposing to form a wild garden will have given proper attention and consideration to the preparation of the soil by the removal of noxious weeds as much as possible, and to the providing the groundwork for the natural relief of the floral colouring a verdure of green lawn or grass.

We have seen many inquiries as to which are the best Grasses to form a lawn, have read the varied answers, and from actual trials can recommend for a good average soil a mixture in about equal proportions of *Agrostis canina*, or *Creeping Bent*; *Cynosurus cristatus*, or

Crested Dogtail; *Festuca duriuscula*, or *Hardy Fescue*; and *Poa pratense*, or *Smooth-stalked Meadow-grass*. We do not add *White Clover*, although some may say it ought to be employed. Let the seeds be sown liberally in April, but before sowing make the ground perfectly even and firm by rolling and raking. Once the greensward or lawn has been formed care must be taken not to fall into the common error of supposing that it will take care of itself. Weeds will assert themselves, and no doubt hand removal will have to be resorted to in order to extract Docks, Dandelions and Daisies, and where moss abounds the surface may require scarifying with iron rakes, re-covering with fine soil and wood ashes, and resowing with fresh seeds.

The practice of wild gardening is yet in its infancy, for the mistake is made in assuming that the mixed border is the only place suitable for hardy flowers. A properly formed and planted mixed border is a charming sight, but when the fact is recognised that this is only one out of a dozen different ways of growing hardy flowers, we begin to see the great wealth of brilliant material available for use in the wild garden in one form or another. Many of the plants are comparatively cheap to buy, easy of culture, hardy, therefore more readily adaptable to the object in view than to any other system of gardening requiring plants of tender constitutions.

We cannot lay down any hard and fast rules to form a perfect wild garden, for no two places are alike; each has its own natural surrounding. Thus we might advise a mixed border of trees and shrubs as a background, where it is needful to hide some objectionable view, while in another case the same would not be admissible. From first to last all appearances of stiffness or formality of outline, either in regard to walks, beds, or borders, should be studiously avoided; Nature should be imitated as much as possible. We cannot entirely dispense with hardy trees and shrubs, neither can we call our wild garden complete without hardy Ferns, or climbing plants festooned, or creeping and trailing plants covering the intervening ground, to enumerate only a part of which space will not permit at present, but more anon. We will for the moment confine ourselves to those plants which may be placed upon the grass portion of our plot.

Here you may produce one of the prettiest and most effective plans of gardening by naturalising patches of such plants as practically take care of themselves. What has so glorious an effect on the green carpet as the golden *Crocus* flaunting its vernal gold to herald the advent of spring, meeting the eye in all odd nooks and corners? while the white *Crocus* are far more telling than *Snowdrops*. Few spring-flowering plants can compare with the *Hepaticas*, varying in colour from a lovely pale blue to a pure white, and shading to mauve and soft pink tints. Of *Narcissus* the varieties are innumerable, and many are worthy of inclusion in the wild garden; but of them all the most deliciously fragrant and most chastely beautiful is the old common white *Narcissus poeticus*. Its beauty and sweetness need no recommendations here; we can only add that it is deserving of more extensive patronage. The common *Daffodil* is equally well known.

Where spring flowers are in request for furnishing cut flowers the charming *Scillas* provide much that may very thankfully be accepted. *Scilla sibirica* is perhaps the best as regards colour, a beautiful azure blue; while the common *Bluebell* (*S. nutans*), so abundant in groves in many parts of England, is worth naturalising, as is also the white variety, *S. n. alba*. Many beautiful and interesting *Primulas* are so fragrant, so excellent in their colouring, and flowering as they do in spring and early summer, that all lovers of flowers cannot forego them. Even the common *Primrose* is a fine object on a good lawn or grass plot. Years ago we remember seeing a large quantity planted out in this way literally covered with bloom. We feel the want of good coloured varieties of this family with the same vigour as the common *Primrose*.

Grape Hyacinths are very desirable in the wild garden. *Muscari botryoides* is well known, and deservedly a favourite with its lively blue globose clusters. We may still find *M. racemosum* in some old cottage gardens growing apparently nearly wild, for it will hold its own anywhere if only permitted to wander over the greensward growing like a weed. The highly interesting and ornamental *Irises* are easily grown, but we rarely see enough of them, and to enumerate or recommend any particular species or varieties would be superfluous, for they are so numerous and all so beautiful. Little need be said in praise of the *Snowdrop*, but still it must be added.

None of the above requires any special attention where the grass is permitted to grow until all the foliage of the bulbs and other spring plants is ripe, when it may be cut over and swept. By spring, when the flowers come up, they should stand out in bold relief amongst the short, fresh, green grass. By no means should the planting be done in driblets. Whatever quantity of bulbs it is decided to put in, plant them in recognisable patches from 1 yard to 2 yards across, and it will be found that none of our spring flowering plants in the border can compare with those grown with grass as a groundwork.—T. GEE.

CYPRIPEDIUM SIR REDVERS BULLER.

THE patriotic martial spirit that pervades members of the British Empire in all parts of the world has made its presence felt in the essentially peaceful circles of horticulture. On every hand we find new forms being named after our leaders in South Africa, and amongst the latest examples we may cite *Cypripedium Sir Redvers Buller* (fig. 9). This magnificent hybrid was exhibited at the meeting of the Royal Horticultural Society, held in the Drill Hall on January 9th, and was recommended for a first-class certificate by the Orchid Committee. The parentage of this *Cypripedium* was given as *C. Smithi* and *C. insignis*. The dorsal sepal is superb. The central colour is bright green, with prominent lines of chocolate-brown spots. The margin is white, flushed with rose. The petals are pale claret, with large varnished brown spots. The pouch is reddish claret. The exhibitor of this *Cypripedium* was Mr. W. M. Appleton, Weston-super-Mare.

CYPRIPEDIUM SEDENI PORPHYREUM.

THE typical *C. Sedeni*—if such a term is allowable in this case—is a very fine garden Orchid, but this variety is a great improvement on it. It bears the same relation to it in a way that *C. aurea* does to *C. Dowiana*, and it is capable of keeping up a longer display than any other kind. For months on end the spikes continue to produce flowers, and these are finer in colour than those of *C. Sedeni*. This is a hybrid that will continue to be grown as a good garden plant, no matter what becomes of some of the expensive rarities that just now are fashion's pets, simply owing to its intrinsic value as an easily grown, free-flowering, and beautiful garden plant.

LÆLIA SUPERBIENS

Small specimens do not show the beauty of this grand *Lælia*, which is certainly worthy of the attention of all who have a suitable structure for its culture. To grow the largest plants

a large house is necessary, but a fine plant of it now flowering does remarkably well in a fernery. The pots must be large enough to take the plants quite easily and allow room for extension, and the compost ought to be rough and open, containing large lumps of burnt clay or charcoal mixed with peat fibre and clean sphagnum moss.

Growers who have had to deal with imported plants know that these are often difficult to get into shape, and with *L. superbiens* the difficulty is greater than with most kinds, for the rhizomes are very stiff, and the pseudo-bulbs large and stubborn to bend. Often it is necessary to cut almost through the rhizomes; and incidentally it may be mentioned that this cutting, instead of injuring the plant in any way, does it good, by causing it to break into fresh growth at places that were previously bare, and by these means makes a more

regularly furnished plant. By pulling down with wire or stout cord the specimens can be shaped a little, and the next time they are potted they may be still further improved by setting some part higher or lower as the case demands.

As to temperature one slightly below that of the *Cattleya* house is best, but the plants will do very well with the *Cattleyas* if no intermediate house is at command. The young growths when forming are usually covered with a gummy exudation that is evidently intended as a protection against crawling insects. Unless this is very plentiful no harm is done by it, but I have known cases where it envelopes the young bud so closely as to hinder its proper swelling, and then it is advisable to sponge it off.

The flower spike is erect from the centre of the growth, and bears upon the apex a cluster of pretty flowers. They are of various tints of rose, and altogether remind one of a large and well coloured *Schomburkia*. *L. superbiens* is one of the discoveries of Mr. G. Ure Skinner, who is said to have first seen it in a state of semi-cultivation by natives in Guatemala. These call it the Wand of St. Joseph, and it is said to grow in great luxuriance in sheltered places, often with flower spikes 12 feet in length. They never attain this size under cultivation.

MR. THORNE'S TREATMENT OF ORCHIDS.

As I expected, Mr. Thorne has set up no out-of-the-way theories with regard to his success with Orchids difficult to grow, and I would like to add my commendation to that of the Editor on page 16. Those who have seen the plants frequently exhibited at the R.H.S. meetings by this very successful grower must have been struck by their singularly healthy appearance, and will be glad to note the simple and observant methods that have led to such excellent results.

DENDROBIUM CRASSINODE BERBERIANUM.

The new year brings us many bright and beautiful Orchids, but none more so than the early flowering section of deciduous *Dendrobiums*. This, it is true, is not yet

in bloom, but the fast-swelling nodes tell of bright things to come in the near future, and the interest of watching the flowers as they develop is great. The variety named above is not nearly as common as many people imagine, and it is the custom of some dealers to mark any fairly good form *Berberianum*. When a true stock of this Orchid is secured it will be found to be one of the finest of the spring-

flowering plants, the bright magenta crimson of the tips of the segments carried well down, and contrasting strongly with the yellow on the lip.

It is not happy in a large receptacle of any kind, preferring small baskets or pans, where the roots reach the sides easily. The type and the variety are both apt to suffer from decay of the lower parts of the stems, and this is always worse when they are growing in large pots. As a companion plant to *D. c. Berberianum*, *D. c. album* may be grown, as the white and bright red forms look remarkably well together, and one helps to show up the other. The cultural details are the same as have frequently been described for other deciduous kinds, the most important points being a quick season of growth, thorough ripening of the growths, and subsequently a proper season of rest.—H. R. R.

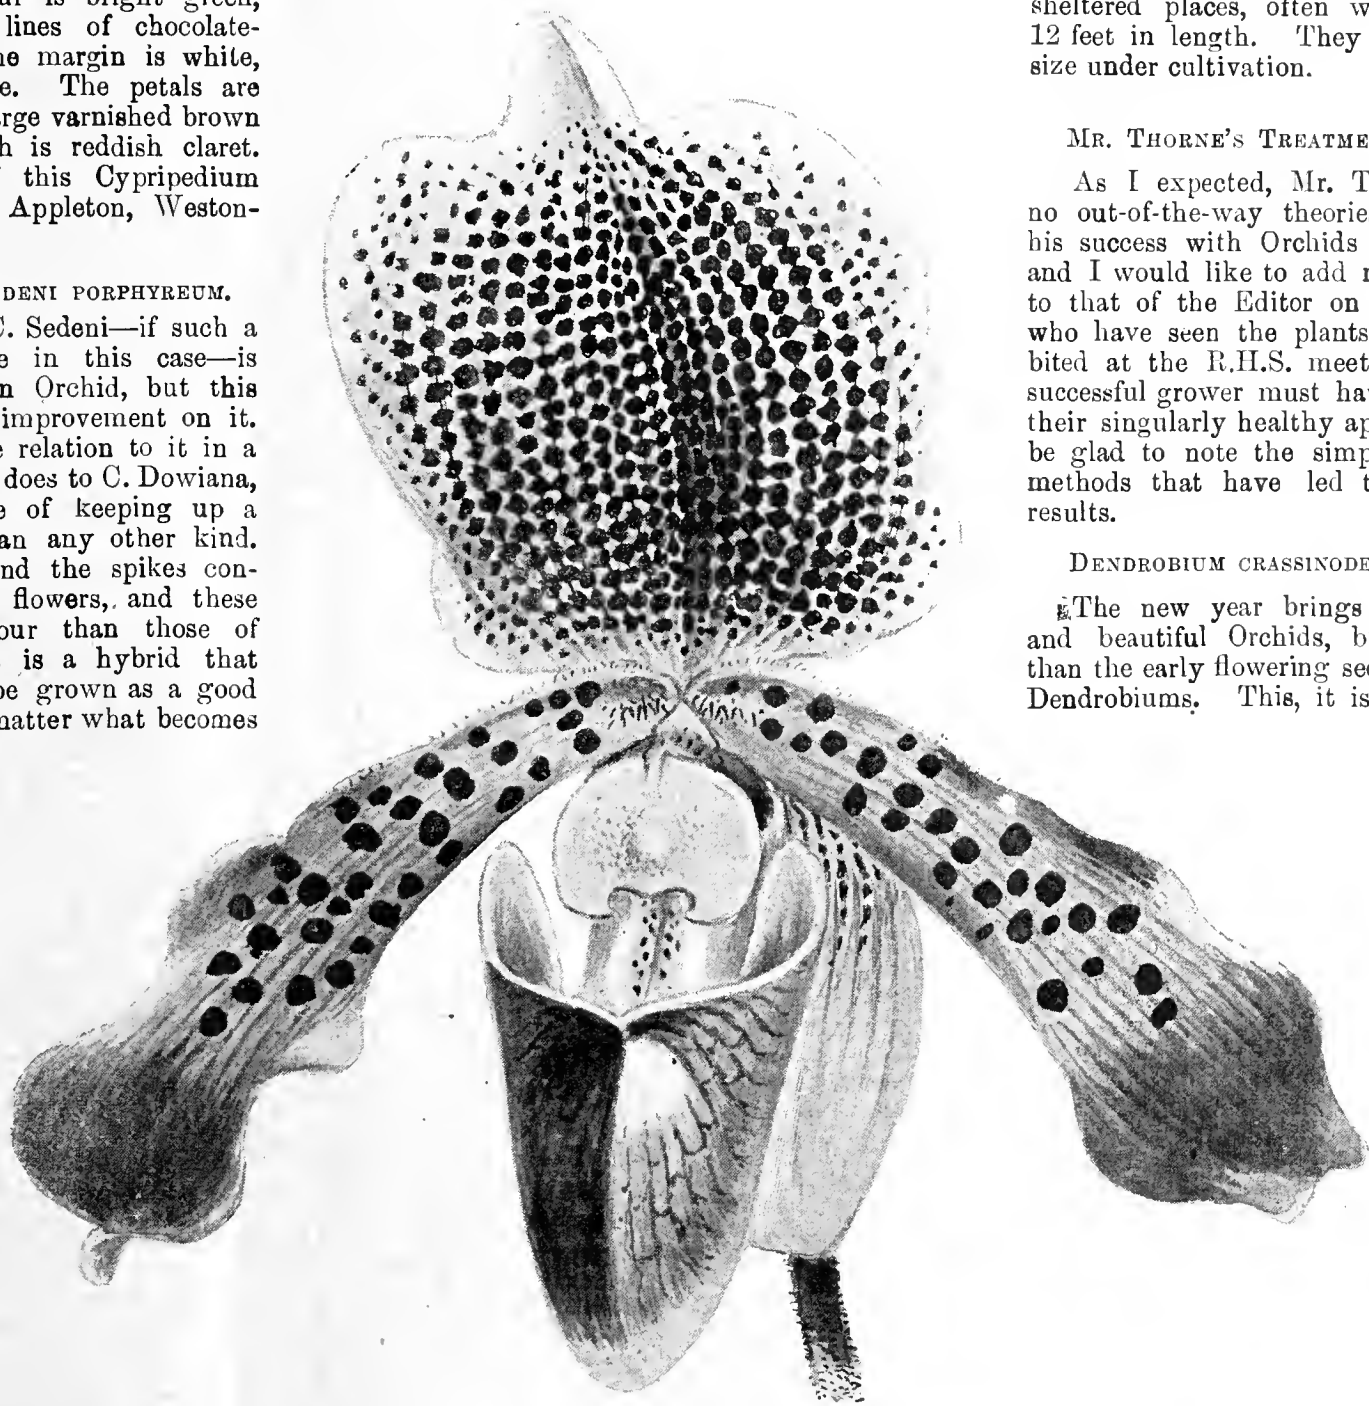

FIG. 9.—CYPRIPEDIUM SIR REDVERS BULLER.

WALNUTS.

WERE it not that it requires a good-sized tree to produce nuts by anything like the bushel in quantity, it would seem a matter of wonder that the Walnut is not in evidence in England to a greater extent, for whether as a fruit or fancy timber tree it possesses a very material value. Doubtless the imported article from France and Spain, which forms part of our winter dessert, is superior to that produced in our own country, and apparently has infinitely better keeping properties, to which latter point I will allude later on. Wherever grown, however, the Walnut is a tree of fairly rapid growth and comes, comparatively, very early into bearing, considering the enormous size to which under favourable circumstances it may eventually attain. My point, however, in this article is rather to remark upon the utilities available to those who are so fortunate to be the possessors of full-sized park or orchard trees in vigorous bearing, than to advocate the advisability of planting, however desirable in itself, which must of necessity be to a large extent a case of doing so for one's heirs.

Apparently (I speak as an amateur merely) English Walnuts vary in kinds to a rather unfortunate extent, that is to say the several indifferent species are hardly compensated for by their sister superior ones. In my own neighbourhood in the Midlands, where fine spreading full-sized Walnut trees are fairly frequent in playing a part of park and ornamental timber, several different kinds are represented.

This autumn afforded a particularly bountiful yield of nuts from all trees. The best perhaps (though I think only from a market point of view) was the Borenut. This is in my own case a really enormous nut, with a double appearance, of a rough and angular shape, but withal a showy and handsome fruit. It shells itself, moreover, remarkably clean. I have found it for an English Walnut fairly easy to preserve. Its exterior, however, rather belies its interior, for it has a superabundance of pulp besides containing much less kernel than one would expect, owing to the space and angularity of its shell.

A truer type of Walnut of a much smaller size, of which I have several very large trees, contains certainly more kernel than the above, though not half its size or weight. Nevertheless this Nut only fetched a third of the price that the other sold for in the market. A third kind I possess in my grounds, but this is of so minute a size as to render them quite valueless, at any rate for market purposes. I am inclined to think people owning Walnut trees do not sufficiently appreciate the value of the crop or take the comparatively little trouble to harvest it. My own trees are partly located in the park and partly in the orchard; in both cases the bulk of the crop is secured by assiduous hunting about under the branches after any wind or frost, and if indeed fully matured a careful picking up every morning. If left on the ground to accumulate they rapidly become black and saturated in the damp and dewy grass. This process, moreover, is assisted and quickened by a thoroughly good shaking, sending a boy as far up the extremities of the branches as is safe, and where he cannot reach or the Nuts refuse to fall from insufficient pressure, quite a little sport and muscular exercise and skill may be developed by shying up with convenient sized and sufficiently heavy pieces of wood. I know the question of thrashing Walnut trees is a somewhat vexed one. Personally I incline to the opinion that not only does it do no harm, but that the unusual friction is beneficial, though in the case of a sound and good-bearing tree it may be well to avoid the sad example of the flourishing young maiden who "was well, would be better, took physic, and died." As with most things it seems superfluous to do other than leave well alone.

Two rather serious enemies, in common I suppose with most others, I have to contend with. Every morning as I dress I have to endure the exasperating sight out of my window of seeing rooks and jackdaws in large numbers and endless procession journeying to and fro with Walnuts in their bills. The quantity they carry off must be simply enormous, and this goes on not only in the early morning, but if undisturbed their depredations are continued pretty well all day. I am told these winged thieves bury the Nuts in the cow manure on the pastures, to find them later when they are pinched for food. The other enemies are, I fear, one's own neighbours, who, as in the case of Mushrooms, seem to regard the Walnut pretty well as their "little perquisite."

A word in conclusion on the question of how to store Walnuts. Numberless ways are advocated, but my own experience is the following as the simplest and most effectual. After being thoroughly dried by spreading them out for preference under a bright sun and breeze, place them in not too thick layers of perfectly dry sand, sawdust, or bran; the latter I almost think is the best, and more likely to keep the nuts free from mildew. This method hardly seems sufficiently well known. My purchaser this autumn, a town fruiterer, seemed surprised at the clean and well groomed appearance of the fruit, and was evidently glad to be told, and recommended this manner of keeping it. The Walnut, however, in a special degree requires considerable care in the storing process. The amount of inherent moisture until

thoroughly dried is really surprising, and its extreme tendency accordingly to mould and decay a source of difficulty, making the fruiterer very shy at buying unless he has a ready and immediate demand. A slight overdoing of it, moreover, in the opposite direction, may very easily dry up the kernel altogether, and render it in consequence valueless.—J. A. CARNEGIE-CHEALES.

EARLY TOMATO CULTURE.

WHERE a temperature of 65° to 75° can be commanded and plenty of light, the present time is suitable for commencing Tomato culture. Plants raised now and grown under good conditions will afford ripe fruit in May and June. Seeds readily germinate in the temperature above named. If sown thinly the seedlings grow vigorously. Heat and light are essential, as well as all the sunshine available, to maintain the sturdy character of the growth. The best plants may be obtained from seed, though cuttings are relied upon for the first crops in some cases, but the plants are necessarily rather long and weakly owing to the winter growth. Few growers rely upon cuttings now. The red varieties are the best for first crops, depending chiefly on Early Ruby, Earliest of All, Winter Beauty, or Ladybird.

The seeds can be sown either in pots or pans, drained well, and filled with a light rich compost mainly consisting of loam, leaf soil, and sand. The seeds are so certain to germinate, provided it is good, that it is worth while to sow it an inch apart on the surface of the soil. Cover with an eighth of an inch of fine soil. Until the seedlings appear uniform moisture may be kept, the best plan being to plunge the pot in cocoa-nut fibre in a bottom heat of 65° to 70°, excluding light also by covering the pot with glass or paper.

In less than a week the seedlings will push through the soil, so the pots must be examined after the first few days, for the moment the seedlings appear they will rapidly elongate if light is not admitted immediately. Transfer the pots to a light, warm position on a shelf, where they will be prevented from drawing out, and thereby kept sturdy. When the seedlings have formed three leaves transfer each plant to a small 2-inch pot, sinking the seedling down to the lower leaves. Return to the shelf, elevating the pots closer to the glass if the shelf is some distance below. When these pots become filled with roots the plants must be shifted into two sizes larger. Still give the plants light and warm quarters, growing them steadily and sturdily until by their vigour and abundance of roots further room must be given.

They may pass into the fruiting pots at this stage, which may be for early crops 9 or 10 inches in diameter. Drain the pots fairly well, placing one large crock over the central hole, and a few smaller pieces over that, covering them with a layer of fibry turf. The compost should be good and substantial, but not over-rich. Two parts of fibrous turfy loam and half a part of decomposed manure, with a similar quantity of crushed charcoal and wood ashes, also a dash of bonemeal. In potting place the plant low down in the pot, and make the compost firm round the ball, just covering the latter with soil after the side space is filled. This amount of compost is sufficient for a start. The pots should be given a warm but sunny position, so that the plants may have all the light available.

As growth proceeds side shoots will issue from the axils of the leaves. These must be rubbed out, and the plants confined to one stem, training this to a stake, eventually to a wire or trellis under the roof. Bunches of flowers appear on the stems midway between the leaves. When the individual flowers are fully open the pollen should be assisted to disperse by shaking the stem at midday, so that the dust-like particles may descend upon the stigma of each bloom and fertilise it, causing the fruit to swell rapidly. The house must be dry at the time the pollen is wanted to disperse. Continue the rubbing out of side shoots, and water sparingly after the final potting until the roots work freely.

An application of fresh compost may be afforded soon after the first bunches of fruit have set. This is a direct encouragement to the surface roots to multiply, and helps the fruit to set and swell readily. Further top-dressings must be given when roots appear freely on the surface of the last application. Additional assistance is given by applying liquid and artificial manures, but it is better to give small or weak, but frequent doses, rather than strong applications. Heat must be given more or less artificially to flowering and fruiting plants until June, after which sun heat is sufficient, though in cold, dull weather some warmth in the pipes would be of advantage in assisting the flower to set. Free ventilation is required by Tomatoes, a constant circulation being necessary in summer.

The temperature required for fruiting plants ought to be from 55° to 65°, ventilating freely on sunny days with a warm dry atmosphere in the structure. A tablespoonful of superphosphate is an excellent addition to every bushel of compost used for top-dressing. If the pots stand on a border of soil after a good crop is set and swelling, roots will pass into the soil and assist the crop.—E. D. S.

NATIONAL CHRYSANTHEMUM SOCIETY.

THE Executive Committee of the above Society held a meeting on Monday evening at Carr's Restaurant, Strand. Mr. Thos. Bevan occupied the chair. The annual meeting was decided to be held at Carr's Restaurant on Monday, the 5th prox., at 7 P.M. The Treasurer then submitted the annual balance sheet, by which it appears that the income for the past year is about £100 in excess of what it was the preceding year, and a sum of £50 is proposed to be added to the reserve fund. On the other side the expenditure for prize money amounted to £508 13s., Secretary's salary £100, and various other charges and expenses incidental to the working of the Society. Altogether it is considered that there is a balance of about £200 in assets over liabilities.

The Secretary then read the draft annual report of the Executive Committee, which referred to the high quality of the Society's three exhibitions, to the work of the Floral and Classification Committees, and to the satisfactory condition of the finances.

Mr. Harman Payne submitted a report from the deputation which visited the French National Chrysanthemum Society's Show and Conference at Lyons last November. Upon the proposal of Mr. Moorman a vote of thanks was passed to the gentlemen who paid the visit, and it was resolved that the report be printed in the new schedule. Certain fixtures—viz., those of the Floral and Executive Committees' meetings—were after some discussion duly made, these meetings being in future, for the convenience of country members, held on the same day of the week. The Schedule Sub-Committee presented an interim report. This involved a good deal of discussion relative to the foundation of an Exhibition Committee, and to the amendments of those regulations relating to the shows.

LATE FLOWERING CHRYSANTHEMUMS.

WE have this week cut fine blooms of Mrs. H. Weeks (taken on second bud) and Georgiana Pilcher, which, at this time when flowers are so scarce, are most useful. Mrs. Weeks, grown on the bush, flowers well at this time of the year; so does the charming single Mrs. Langtry, which at the present time is in full bloom, and with its lovely perfume is the delight of the ladies. I find cuttings of the latter inserted in May, and potted in 7 and 8-inch pots, do well, and come in late.—G. CARVILLE, *Duncombe Park Gardens, Helmsley.*

CHRYSANTHEMUMS IN JAPAN.

AN American lady in Tokio, Japan, has sent to her friends a very entertaining account of the home of the Chrysanthemum, its people and their customs. Among other matters reference is made to our favourite autumn flower, and the "American Florist" is indebted to E. G. Hill of Richmond, Ind., for permission to print therefrom the following descriptions of a Chrysanthemum exhibition, and one of the finest private collections of these plants in Japan:—

"Last Wednesday we went to Dangozaka to see the famous Chrysanthemum show. Dangozaka is a park in the city, about six miles from here, full of interesting temples and trees, but the most attractive thing at present is the street. All along down this lane or street are side shows, admission to which costs five cents, and there one finds all sorts of legendary history carried out in Chrysanthemums. There are wire forms, for instance, of a man, woman, boat, and house, and the Chrysanthemums are trained from the beginning over these wire forms. The roots being inside, the dress, for example, of a woman, sleeves, sash and all, are one mass of colour, and at a distance look like changeable silk. Very small varieties are used, but in all colours imaginable. The forms are all life size. For instance, one very fine figure was that of a Japanese warrior slaying a mammoth dragon, all in flowers except the face and hands, which were of wax. In one place they have represented the famous waterfall at Nikko all in white Chrysanthemums, and the spray and waves at the foot of the fall are almost perfect. Then there was a big boat, all of the flowers, in big waves, with life-size figures in it, and the whole thing, figures and all, worked by machinery. A man sat down and told the history of all these things. All I can say about it is very far short of the reality. No one can form any idea of the real ingenuity of these people unless one really sees it. The individual flower they do not care for, it is the way they can train them that receives their admiration."

Referring to the gardens of Count Okama the writer continues:—"The entrance to the grounds is beautiful, such hedges, such trees

were never trained in America, such picturesqueness was never seen out of Japan. I cannot go into detail, but will try to tell about the Chrysanthemums. The plants are in sheds made of bamboo, and immaculately clean and tidy. There were six sheds altogether, one devoted to wild Chrysanthemums entirely, one to those that are trained up to bear one flower only, but not one equals those we have seen at home. Count Okama's secretary says they care least for that part of the cultivation of these plants. Each flower is on a wire frame, and the petals all combed out on the frame.

"In one shed were three plants, a white ragged variety and two red ragged ones; they are trained in a wire frame, and one plant has over 1000 blooms, each bloom is at the end of a single stalk, and all this from a single root. It is fully 15 feet across. In fact, a short distance off it looks like one mammoth bouquet of flowers, or rather like one big flower. The flowers themselves all are about the size of the palm of the hand. Another shed has each plant trained to fourteen blooms arranged as a picture; they are rare sorts, and the plants are raised in back and diagonal rows. It is a beautiful sight, and very pleasing after one gets used to the conventional way. Another house has one big plant, and from a single root there are forty varieties and colours of flowers, all having been grafted upon the single root. It is marvellous, and there is no sham about it, for one can see the root and trace the flowers. It looks like a huge bouquet of all colours. Then there were two immense balls, at least 4 feet in diameter, each colour in sections like an Orange, with a bow knot of flowers at the bottom, all growing inside, but a solid mass of bloom on the outside."

WINTER ACONITES.

ALMOST as soon as the new year opens the golden flowers of the Winter Aconite begin to thrust themselves through the soil. Protected from defilement by the blackness of Mother Earth as they force their way through the ground, the little Elizabethan ruffs, which shield the flowers at that period of their career, serve afterwards as ornaments to the golden blossoms. They are small and unassuming these Winter Aconites, yet their beauty in a mass is only equalled by the cheerfulness they inspire by their gleams of gold when the garden is otherwise dull and bare. They are harbingers of the bright flowers of spring and summer, and show us that golden colour which brightens our hearts with the summer sun.

It is strange how some despise the Winter Aconites. They are too cheap to be exclusive, they are too hardy to give trouble to grow, and they are not exotics, but thrive in our own dear land. These things are against them being found in many gardens of the exclusive, but they are their passports to the hearts of the numbers who care for the modest beauty of our simple hardy flowers of spring. It is somewhat anticipating things to speak of *Eranthis hyemalis* in connection with the word "spring;" yet spring comes with the Snowdrop and the Winter Aconite, and does not dally until the last frosts are away, and the sun is warm, and the breezes balmy and mild. Thus one would speak of them now, when their coming is at least nigh.

Although not believed to be a true native, the *Eranthis* is naturalised in some places in this country, where it has been so long that it may be said to be as truly British as some of our families, whose descent can be traced to some ancestor who established himself in "this seat of Mars" from across the silver streak, which is our barrier from the outer world. The Winter Aconite has so long been with us that we look upon it as of native birth. We rejoice when we see its bright flowers, for they tell us of the crowds of blossoms which come behind.

When one has penned this appreciation it seems superfluous to say aught about the flower and its wants. It demands little from our hands. A moist rather stiff soil is what it likes, but it will content itself, and be happy, too, in a lighter one. With moisture and shade it can do without the stiff soil, but it resents having its tubers dried by the summer's drought. One has experienced this in hot and dry seasons, such as sometimes fall to our lot. The Winter Aconite should never be kept long out of the soil, and ought to be planted as early as possible after the pretty leaves die down.

It may be too common to take up for itself a large space in the garden, yet it need not altogether monopolise all the space in which it grows. It may be planted among other plants, which will occur to those familiar with flowers, whose blooms would succeed those of the *Eranthis*. I have a bed of Winter Aconites and Lily of the Valley in a shady corner. There the two are in happy companionship, the cups of the *Eranthis* passing away long before the bells of the *Convallaria* appear. If the leaves of the Winter Aconites are not away when the Lily of the Valley comes into growth they are soon hidden by the shapely leaves of the "naiad Lily of the Vale," as Shelley calls it.—S. ARNOTT.

THE VALUE OF DRAINAGE.

THERE are some matters of equal importance to the gardener and the farmer, and this is one of them. Who can say how many acres of land there are now lying waste and profitless that only require the work of the drainer to carry off the superfluous water in order to make it fertile and yielding? It is unreasonable to expect a cold water-sodden soil to be profitable to either gardener or farmer, and it is surprising how many presumably practical men there are who continually chafe at disappointing results without ever considering this simple but important reason for the failure.

During the past few dry seasons the importance of thorough land drainage has not been so apparent, but it makes no difference to the fact, and one cold wet summer would bring it before us in all its significance. Fortunately for the appearance and fertility of the country the larger proportion of land drains itself naturally, and by the suitable formation of the substrata the moisture, after performing its functions, is carried away. I say, fortunately, because if it was not so we should have many more of those dreary, unfertile areas of land that grow nothing but clumps of rushes and wiry grass, which are to be seen in all districts, and are as unsightly to the landscape as they are useless to the cultivator. Illustrations such as these, and the difference to be seen after the superfluous water has been carried away, point more plainly to the fact that good drainage is one of the first principles of land cultivation.

And yet how often it is overlooked! More than once I have seen instances where well-meaning persons have spent time and money in planting fruit trees, and the capital has had to be written off as a dead loss. A few years have seen healthy vigorous trees transformed into miserable cankered specimens with gaps here and there showing where they have succumbed, while the would-be fruit grower in time gets tired of waiting for improvement and throws the whole thing over as a bad job. Due regard for the first principles of cultivation might have saved all this, and a few pounds spent in drainage at the outset would have been money well invested.

The county of Kent has a wide reputation for the production of fruit, and its climatic advantages and fertile soil are often referred to as being the direct causes of it. Quite so, but we must not overlook the fact that a greater part of the county, and particularly that where the most fruit is grown, has a perfectly natural drainage in the substrata of chalk which exist, and consequently the soil has every opportunity of being warmed and rendered free and friable. All the same, there are many instances of fruit failures in this favoured county that can be directly attributed to superabundance of water in the ground, and to the wrong impression held by some persons that because Kent is a fine fruit producing county it can be grown everywhere.

One might readily carry the argument from fruit grown outdoors to that under glass, where good drainage is all-important. Shanking of Grapes and other Vine failures may more often than not be traced to defective drainage, followed by the consequent sourness of soil, and whole or partial failure of root action. I wonder how many cases there are to-day of sickly Vines where growers are doing all they can to improve matters by feeding and treating the parts that are visible. And the task is a thankless one, for the evil lies deeper, underneath the border in fact, where clogged or defective drainage no longer acts as a water conductor, but as a barrier, whereby the periodical applications made to the roots are conserved instead of being carried away, and under these conditions it is only a matter of time for the best of composed borders to become sour and sodden instead of a healthy feeding ground for fibres. We often hear complaints about worn out Vines, though no one has yet been able to determine how long a Vine is capable of producing high quality Grapes provided all conditions are satisfactory, and it is quite reasonable to conclude that many so-called worn out Vines are brought into that condition through defects in the drainage system of the borders.

It is the same with other fruits grown under glass. Take Peaches and Nectarines for instance, and their failure to ripen the young wood and produce fruit blossoms. It is not so much the water they receive as the fact that the moisture cannot get away but remains to sour the soil. Nature teaches the lesson, because with fruit growing out of doors wood rarely fails to ripen and produce fruit buds, even in wet seasons if the drainage is good, and it is only where the latter is defective that the evils mentioned above become apparent.

As a final illustration, how important it is that the drainage of all plants in pots should be good, and particularly so during the winter months. Who is there among gardeners who has not seen Heaths and Azaleas die in a mysterious manner, and pot Camellias turn sickly and drop their buds, and all because the water after performing its purpose cannot pass freely away? Softwooded plants succumb from the same cause, and defects in drainage frequently result in wholesale losses of Cinerarias and similar plants which require careful treatment through the winter months. Crocking a pot is in itself a

simple operation. It is the first lesson a garden boy learns, and one of the most important, and often the man who plies the water can is blamed for the shortcomings of the one who crocked the pots.

Thorough drainage then is indispensable in all cultural departments, and no substitute can be put in its place. Where Nature does it herself, all well and good, but where it becomes part of the work of the cultivator let it be understood that there are two ways—the right and the wrong. The former is conducive to the best results, the latter courts failure, and any attempt at a middle course is risky, if not dangerous.—H. H.

EXPERIENCE WITH CLUBBING.

AN ANCIENT REMEDY.

ON points of the nature referred to on page 36 last week on the extraordinary case of clubbing on Apple roots, there is no guidance so safe as that of experience. Perhaps I may usefully refer to a case of clubbing or finger-and-toe in Turnips that occurred long before the disease was proved by M. Woronin, a Russian botanist, in 1876, to be due to a slime fungus, *Plasmodiophora Brassicæ*, and even before the Rev. M. J. Berkeley expounded the nature of the Potato murrain in 1846. It was in 1844 that, as in previous years, Turnips finger-and-toed on two plots of land of a light sandy nature, every year cropped with Ashtop Potatoes, a second crop of Potatoes for seed being taken on one plot and Turnips on the other in alternate years.

The Potato epidemic ended the second cropping with Potatoes in 1846, and in that winter (1846 and 1847) one of the plots was marled at the rate of a hundred cartloads to the acre. I remember it well, for to a lad of nine years throwing lumps of clay marl about was no joke. The weather broke the lumps up beautifully, and a dry time being chosen for ploughing in, the leader of the horse was not hampered by pounds of clay adhering to each foot. The plot was planted with early Potatoes, and given a dressing of half a ton of salt to the acre. This perhaps did more harm than good, as the disease was rampant among them.

Turnips followed the Ashtop Potatoes, and they did not finger-and-toe as before; then, cleared of the Turnips in October, the land was ploughed and sown with Wheat on November 5th, 1847, and in 1848 there was a heavy crop, as I had reason to remember, as I cut my hand to the bone in letting the sickle run up the straw instead of bending the latter over in shearing. Output 60 bushels of Wheat per acre, and tailing for grinding to mix with "demicked" Potatoes after boiling, to fatten pigs; there was no more finger-and-toe amongst Turnips on that plot of ground.

The other plot was dressed with salt, half a ton to the acre, after the Ashtop Potatoes, then sown with Turnips, and two-thirds of the crop decayed on the land. A breadth of Cabbage, however, did not club, for the land where they were grown was dressed with a mixture of soot and lime mixed with salt from cured bacon. At that time I knew as much about club fungus as about growing Cabbages and Turnips; but I had a microscope, even in those days, but of low power, and it failed to bring into view anything but what I afterwards learned was a naked mass of protoplasm. A dressing of gas lime—a cartload to the rood, for that was the extent of this plot—enabled us to grow Turnips after the Ashtop Potatoes.

I have often pondered over these experiences of early days, and wondered why so very few persons now-a-days dig marl pits and chalk pits. In olden time they were common; light land was clay marled and hot land chalked. The finger-and-toe came in with the field culture of Turnips about 1645, but appears to have made very little advance until marling and liming passed into oblivion. Now we discover that land wants lime to provide wholesome nutrition for useful crops, and our discoveries simply enforce the wisdom of ancient practices, and experience proves that they cannot be disregarded without prejudice. With all our boasted advancement we still have to dig the soil "deeper to find the gold"—the inorganic elements for blending with the organic accumulations of ages.

Of all correcting substances lime appears the chief. It was the lime of the marl that enabled the Turnips to resist the slime fungus, just as the cyanogen of the gas lime killed the parasite on the other plot and improved the land for producing Brassicas.—G. ABBEY.

WATER EXPANSION.—It was an odd coincidence that on the day the last issue of the Journal came to me that I should have also seen in the month's issue of the "Strand" an illustration of a jug which, left exposed to severe frost for one night only, and full of water, was shown with the water a solid block of ice, and the jug split in halves. That was singularly conclusive as to the distension of water which takes place when it is solidified by frost. There were also, oddly enough, in the number illustrations of a ship in different stages of sinking because the ice in the northern regions had crushed in the side of the boat, and thus admitted water. Of course, object lessons of this kind are not required by those who do know, but there still seem to be some people in the world who need such proofs to convince them.—A. D.

Recent Weather in London.—On Saturday morning last there was a general frost over the whole of the metropolis, and it kept clear and bright throughout the day. Sunday was brilliantly fine, but during the early hours of Monday morning rain fell heavily, and continued at intervals until midday on Tuesday. After this time, though nothing more than a drop or two of rain fell, it was dull, unpleasant, and very enervating. On Wednesday morning, at the time of going to press, it was very dull.

Royal Horticultural Society.—The next fruit and flower show of the Royal Horticultural Society will be held in the Drill Hall, James Street, Westminster, on Tuesday, January 23rd, 1 to 4 p.m. A lecture on "The Neglect of Flowering Shrubs in Gardens" will be given at three o'clock by Mr. Geo. Bunyard, V.M.H.

Shirley Gardeners' Association.—The monthly meeting of above Society was held at the Parish Room, Shirley, Southampton, on Monday, 15th inst., Mr. B. Ladhams, F.R.H.S., presiding. Mr. W. Middlebrook, of Messrs. Veitch & Son's Nursery, Chelsea, was to give a paper on "Pear Culture," but being unable to attend, his carefully prepared document was read by Mr. G. Miles, The Gardens, Portwood Park. The paper dealt with the soils, subsoils, position, planting, climate, stocks, pruning, diseases, and insects. A good discussion ensued.

Columbines.—Except to the botanists *Aquilegia* species have far fewer charms for the gardener than have the more popular hybrids of species, so plentiful, so far as seed is concerned, although not half so widely grown in gardens as they should be. These hybrids seem to have collected through intercrossing, all the forms and colours found in the named species, with many more hues and combinations. The best time to obtain seed for sowing is in the spring. As a rule the seed ripens rather late for sowing outdoors the same season, but some sown in pans or boxes in September under glass will give strong plants to put out the following April. I greatly prefer to have strong plants to put out where they are to bloom in September, as these flower very finely the next year, whilst late seedlings too often fail to bloom in the third year.—A. D.

Spring Planting Trees.—Though what Mr. A. H. Pearson has written in relation to tree planting is correct, the majority of gardeners will continue to prefer doing that work in the autumn, whilst the soil is yet fairly warm, rather than in midwinter or in the spring. But let the season be what it may, so much of success after planting depends on the care exercised in lifting first, and the shelter given to the roots when lifted next, ere the replanting is done. Trees lifted in a nursery can be replanted as fast as lifted. But when they have to be sent long journeys by rail, and are some three or four days *en route*, then roots suffer very much, especially if exposed to the air. When received it is wise to stand the roots a few hours in water to enable them to become plump before the planting is done. I do not at all think there is really any planting now done in holes the dimensions of a silk hat. The metaphor may do to point a moral, but like not a few others it is somewhat exaggerated.—A. D.

Kalanchoe flammea.—The figure of this plant on page 27 gives a good idea of the light airy appearance which it possesses, but cannot convey to the reader's mind the beautiful orange scarlet colour of the flowers. Those who saw it in flower at Kew or at the Chiswick Conference on Hybridisation will need no farther inducement to obtain it as soon as possible, and those who were not fortunate enough to see it may be firmly convinced that it is one of the finest introductions of recent years, and will prove invaluable when we have mastered the details of its cultivation. It must not be confused with another species of this genus which was introduced some few years ago, and now appears to have dropped out of cultivation. That plant was easily grown, but the flowers lacked colour and proved worthless for all practical purposes. The present species promises to be as great in success as the other plant was in failure.—W. H. DIVERS, *Belvoir Castle*.

Death of Mr. Thomas Harkness.—This well known nurseryman passed away at Oakfield, Hitchin, on Wednesday, December 27th, 1899, at the advanced age of eighty-two years. The deceased retired from business about twelve years ago.

Park for Edmonton.—Pymmes Park, a residence and estate of 53 acres, has come into the possession of the Edmonton District Council, which has acquired it for £36,000 for the purposes of a public park and recreation ground. The estate is well wooded, and contains a fairly large sheet of water. It is situated in the heart of a rapidly increasing neighbourhood. The Middlesex County Council has contributed £6000 towards the purchase, and grants have also been made by the Metropolitan Tramway Company, the City Corporation, and the City Parochial Foundation.

Reading Gardeners' Association.—There was a large attendance of members at the fortnightly meeting of the Reading and District Gardeners' Mutual Improvement Association on Monday evening to hear Mr. G. Hinton of Walmer Gardens, Reading, read his essay, which was awarded the first prize in the recent competition, "The Planting of a Garden with Hardy Fruit Trees and Bushes." The paper gave rise to much criticism, and during an hour and a quarter's interesting discussion many points on planting, manuring, and pruning were touched upon. A hearty vote of thanks was accorded to Mr. Hinton for reading his paper, and to Messrs. Bunyard & Co. of Maidstone and the Hon. Sec. for presents of books to the library.

The New Year for Tree—Mother Nature has just celebrated a birthday, for according to the "Jewish World" Monday was the fifteenth day of Shebat in the Hebrew calendar, and the New Year for Trees. Our contemporary points out that of the four new year days ordered by the Talmudio authorities none is more apposite than this one, which reminds that the longest nights are over, that the sun renews its warmth, the forests throw off the lethargy of winter, and the sap begins to rise in the trees. The Rabbis recognised the dulling influence of the shorter days and the exultation of the brighter season, and commanded this simple festival of recognition of the operations of Nature. As contrasted with heathen beliefs at the period when this celebration was inaugurated, our contemporary says "it should be found that this festival of the trees' birthday has had no little share in the destruction of superstition among the Jews, and especially among the Jewish peasantry. To-day only the calendar and its observances recall the life of far-off days; but it is well that the calendar should stimulate us with such memorabilia.

Warranty of Seeds—A Wrong Crop.—Mr. Justice Channell had before him recently, in the Queen's Bench division, the case of "Howcroft and Another v. Perkins," which was an action brought by the plaintiffs, seed merchants, against Mr. G. Perkins, a nurseryman and market gardener, to recover the balance of an account for goods supplied. Defendant admitted the claim, but set up a counterclaim which raised a point of considerable interest to seed merchants, nurserymen, and others. It appeared that in October, 1898, the plaintiffs' traveller called upon the defendant and obtained an order for certain quantities of seed, including 1 lb. of Clayworth Prize Celery seed, the price of which was 3s. The defendant said that instead of supplying him with what he ordered the plaintiff sent him Turnip-root Celery seed, with the result that the plants which he reared, numbering 14,000, only realised 6d. per dozen instead of 1s. 6d. The defendant contended that the plaintiffs' traveller warranted that he should have what he had ordered, though he admitted that the invoice sent by the plaintiffs after the goods had been delivered contained a clause to the effect that the vendors gave no warranty, express or implied, as to description, quality, productiveness, or any other matter to any goods sent out. They would not be in any way responsible for the crop, and if purchasers did not accept the goods on these terms they were to return them. Plaintiffs denied that there was any warranty, and contended that the defendant was bound by the terms of the invoice, which were common in the trade. They further said that unless they were protected by these terms they would have to go in for an extensive system of insurance. In this case the plaintiff purchased seed of the value of 3s., and alleged that he had sustained damage of about £60. Mr. Justice Channell gave judgment for the plaintiffs, holding that the terms contained in the invoice were reasonable and binding upon the defendant. Judgment accordingly for the plaintiffs on the claim and counterclaim with costs.

Bristol Gardeners' Association.—The fortnightly meeting of the Society was held at St. John's Parish Room, Redland, on Thursday, January 11th. There was a good attendance, Mr. C. Lock presiding. Mr. Garnish of Stapleton read a paper on the subject of "Strawberry Culture." He recommended a soil of clay, neither shallow nor stiff, to be well trenched and manured, and runners to be laid in June for planting at a distance of 2 feet apart. He urged the frequent use of the hoe, and gave many helpful suggestions, for which he was heartily thanked. Prizes for six dessert Apples were secured by Mr. Marsh, first, and Mr. Sutton second. Certificates of merit were awarded Messrs. M'Culloch and Clark. A special feature of the exhibits was a fine collection of Apples staged by Mr. Bannister of Cote House. It consisted of nearly thirty varieties of choice fruit, and was much admired by the members.

The R.H.S. Meetings.—At the Drill Hall meeting, on the 9th inst., the members of the Fruit Committee invited the Chairman, Mr. P. Crowley, to convey to the Council the feeling of the Committee, that one meeting in each of the months of December and January was ample for all ordinary purposes. Not only does the expenditure incurred over such meetings, that are such poor ones, prove superfluous, and indeed wasteful; but the bringing of a large number of members of the Committees to the Drill Hall for no better purpose seems wasteful also. No doubt the inclusion of two meetings into December and January for the first time, as now seen, is due to the importunities of the orchidists, but certainly not to anyone else. It is not fair to Fellows to announce these meetings, and then furnish so little to be seen. If to orchidists two meetings during each of the midwinter months be desirable, their requirements might be met in the Council room in Victoria Street.—A. D.

The Ancient Society of York Florists.—The annual meeting of the Ancient Society of York Florists was held on January 9th in the Agricultural Club Chambers, Pavement. Mr. Ald. McKay, J.P., presided over a good attendance. The Secretary (Mr. G. E. W. Oman) having read the minutes of the last meeting, presented the report. They were very pleased to state that the year's working, all things considered, was most satisfactory. The number of members who had paid their subscriptions during the year was 732. This, with twenty-one new members to be added to the list, made a membership in excess of that of any previous year of the Society's history. The total receipts had been £628 12s. 2d., an excess of £62 17s. 4d. over last year's receipts; but the expenditure had been £653 2s., an excess of £117 15s. over last year. Of that amount £57 13s. had been expended in prizes, and there had been some items of expenditure which would not occur again. Mr. G. Lamb, Hon. Treasurer, submitted the statement of accounts, which were taken as read. The Chairman, in moving the adoption of the report and balance-sheet, said he observed a slight deficit on the year's working amounting to £23 9s. 11d. He did not, however, think they need be under the slightest misapprehension. Mr. W. B. Dyson seconded the resolution, which was passed unanimously.

Sprouting Potato Sets.—As an old Potato grower I am somewhat amused to learn that our American friends have been experimenting as to the comparative values of planting properly sprouted and of non-sprouted Potato sets. I had imagined that such an acute people had determined that matter long since, just as we have. I do not suppose that even the most elementary gardener doubts the great value of planting sprouting Potato sets over those that are unsprouted. It is a matter we have settled to our satisfaction years ago, but is only satisfactory when the sprouting is natural and not artificial. Almost any Potato will throw sprouts in a normal temperature towards the end of the winter. The great bulk of early and midseason varieties where properly exposed to ample air and light will do so by the end of January, except when the temperature is unusually low, but that does not often occur. Even when we have hard winters we get some soft, mild periods, and these provoking great reaction from the low temperature, compel the sets to burst buds early. It is, however, only needful that these sprouts when formed be fully exposed to the light in a cool place, and they will remain sturdy, stout, and deep coloured from the first bursting period until the sets are planted. Nothing is more natural than that they should be productive of earlier growth than results from tubers non-sprouted. Practically the sprouts represent fully three weeks advanced growth; still, farther, they represent average even growth from all the sets, and that is far from resulting when non-sprouted sets are planted.—A. KINGSTON.

Finsbury Circus Garden.—We learn that at the annual meeting of the freeholders and leaseholders of Finsbury Circus, held recently under the presidency of Mr. Gordon Brown, it was resolved to oppose the Bill which is being promoted in Parliament by the Corporation to throw open Finsbury Circus Garden to the public. Only a very small number of the inhabitants can legitimately take part in the opposition, as the Corporation's new leases contain a stipulation that the leaseholders shall not oppose the Corporation in the matter.

American Tomatoes.—It is reported that the Tomato crop of southern New Jersey the past season amounted to 850,000 bushels, while there were also abundant crops of them in other parts of the State, on Long Island, and many sections in New York State. As a result, the price was down to 15 or 20 cents a bushel much of the season. If there had not been a comparatively small crop of Peas and Beans, which obliged the canning factories to put up more Tomatoes than usual, it is doubtful if they could have sold at any price. We remember, says the "American Agriculturist," when few of our friends and neighbours could be induced to eat a Tomato under any consideration. Now it is seldom that we see anyone who does not like them. About 12,000,000 cans of Tomatoes are packed in a season in New Jersey, and about 126,000,000 in the United States. The canning process enables the poor man to have these and many other vegetables and fruits on his table every week in the year if he pleases, at a moderate cost, while it also helps the farmer and gardener to sell their crops in a time of plenty at better prices than they would get if only wanted for immediate use.

Clenkowskia Kirki.—Complaints are sometimes heard about this plant, and others nearly related, not flowering as freely as is desirable. This in many cases is due to it not being properly rested in some cases, I imagine, and certainly was this the fault in some plants I was asked to look at recently. With fair treatment there is no easier grown plant, but it is more truly herbaceous than many plants in the same order. The underground rootstock may be kept quite dry from the time the leaves die off until the early spring, when it may be repotted and gently excited as the leaves push up. It likes a fairly substantial compost, one containing a fairly good sprinkling of half-decayed manure, and if propagation is desired this may be effected by division of the roots at the time of potting. Increase the moisture as the leaves push up, and when the pots are full of roots feed rather liberally. The pretty blossoms are produced from March onward to July and August, according to the time of starting, midsummer being perhaps the most natural time. The peculiar centre to the flower bears a strong resemblance to the column of an Orchid, and the whole flower might easily be taken for a *Miltonia*. Beside this there are several others in the genus, many being remarkable for their fine foliage.—R. HENRY.

Frost and Shrubs.—It will be interesting to learn how far the recent frosts, which seem to have been exceptionally severe in some places, have left their impression on hardy shrubs. Mr. W. Pope writes me from Highclere Castle that he never saw common Laurel injured to so great an extent as now, the effect of the frost on the late and immature growths following in the autumn upon the September rains. During the frost there was at Highclere a heavy coating of snow over vegetables, or otherwise the injury done to those would have been great. As it is, both white Broccoli and Brussels Sprouts are much cut. He mentions a fear that *Laurustinus* are killed to the ground. That was hardly anticipated as likely to follow upon so dry a summer. I remember the terribly severe frost of Christmas eve of 1861, which is thirty-eight years ago, when such terrible havoc amongst shrubs was made, and many assumed hardy things, especially *Laurustinus* and Bays, were killed wholesale. I do not think such harm has been done to shrubs since then; but that frost followed upon a rather cold, wet summer, and went down to zero. At Highclere the frosts registered 22°, 20°, and 17°, which was fairly severe. We have had far severer frosts than these; but it is not always the most intense frost which does the greatest harm to shrubs. Highclere lies high and bleak; yet at Sydmonton, a few miles distant and lower, Mr. Lye registered 29° of frost. No doubt, one reason why frosts sometimes do so much unlooked-for harm is the intermittent nature of the weather. One week soft, mild, and the glass standing at 50°; the next week the glass is down to 10°, a difference of 40°, and enough to cause great harm to result. Gardening in Britain finds fewer difficulties to encounter than is presented by the climate, because it is so uncertain and unreliable that no one can say what the morrow may bring forth.—A.

Isle of Wight.—The sixth annual meeting of the Isle of Wight Horticultural Improvement Association was held at Newport Town Hall on Saturday last. Dr. J. Groves, B.A., J.P., presided over a large attendance of members. After the minutes of the last annual meeting had been read and passed, the Hon. Secretary read a lengthy report of the work done during 1899, dealing with the finances, in which there is room for improvement, and of the excursions, which numbered six. A spring show was held at Ventnor, and a fruit show at Ryde. The membership roll has gradually increased from 308 to 427, a gain of 119 members. The report was adopted on the motion of the Chairman, after which the election of officers ensued. After the election of several new members, a social entertainment was held at Warburton's Hotel, at which songs and recitations were given by the members. The year has been one of progress for Island horticulture.—S. H.

December Weather at Hodsock Priory, Worksop.—Mean temperature of month, 34.3°. Maximum in the screen, 54.6° on the 4th; minimum in the screen, 64° on the 14th; minimum on the grass, 6.7° on the 14th; number of frosts, in the shade, 17; on the grass, 27. Sunshine, twenty-eight hours, or 12 per cent. of the possible duration. Rainfall, 2.33 inches. Difference from average, 0.23 inch. Rain fell on eighteen days. Maximum fall, 0.54 inch on the 28th. Rain from January 1st, 22.27 inches. Difference from average, 3 inches. The coldest December since 1892. Mean temperature, 10° lower than last year.—J. MALLENDER.

December Weather at Dowlais.—Rainfall 4.33 inches, which fell on twenty-one days; snow on eight days. Greatest rainfall 1.35 inch on the 28th; greatest snow 0.44 on the 11th. Temperatures: mean maximum 35.065°; highest reading 47° on the 1st, and did not rise higher than 23° on the 14th. Mean minimum 23.323°; lowest reading 7° on the 14th; below freezing point twenty-eight nights, and below 32° on thirteen days. The prevailing direction of the wind was N.E. and E. There were twenty-one sunless days. Very rough day on the 30th, with hail, rain, snow, thunder, and lightning at about 7 A.M., finishing with a sharp frost at night. Rainfall for the year 52.45 inches, which fell on 168 days. Average for the past thirteen years 48.051 inches.—WM. MABBOTT.

December Weather at Belvoir Castle, Grantham.—The wind was in a southerly direction twenty days. The total rainfall was 1.98 inch. This fell on fifteen days, and was 0.10 inch below the average for the month; the greatest daily fall was 0.46 inch on the 29th. Barometer (corrected and reduced): Highest reading 30.537 inches on the 3rd at 9 A.M.; lowest 28.355 inches on the 29th at 9 P.M. Thermometers: Highest in the shade 54° on the 7th; lowest 11° on the 14th. Mean of daily maxima 39.67°; mean of daily minima 29.00°. Mean temperature of the month 34.33°. Lowest on the grass 8° on the 14th; highest in the sun 85° on the 4th. Mean temperature of the earth at 3 feet 41.80°. Total sunshine, forty-four hours fifteen minutes. There were fifteen sunless days. The barometer reading at 9 P.M. on the 29th is remarkable, it being the lowest recorded here since June, 1894, previous to which date our records are imperfect.—W. H. DIVERS.

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet.

The weather during the first part of the week was dull and showery, the latter part being fine and bright, with very cold winds.

A Botanical Laboratory for Liverpool.—It is announced that Mr. W. P. Hartley, the well-known jam manufacturer at Aintree, is about to give £12,000 to build and equip a botanical laboratory at University College, Liverpool, in connection with the botanical school. This is the third gift from the same donor to the city.

Virginia as an Apple-producing State.—The Virginia State Commissioner for Agriculture, Hon. G. W. Koiner, issues an elaborate report from his department. It is freely illustrated. The Commissioner thinks that in ten years Virginia will be the greatest Apple-growing state in the Union. The trouble at present seems to be that the trees are not taken proper care of. If spraying was in general use in this state, as it is in others, the yield of many orchards would be increased 25 per cent., and the fruit therefrom would be of a quality to command the highest market prices.

Careful Gardening.—It is often said against amateur gardening that flowers, fruits, and vegetables can be bought in market cheaper than they can be raised. In some respects this is true; but usually the amateur is a long way ahead in the superiority of the articles. This is strongly in evidence by articles found in English markets. Though steam and electricity are pouring the best of their products from favoured orchards into England they are tame compared with that artificially raised by the best English gardeners. In the early part of July Peaches that would ordinarily be pronounced first-class, from Italy and other Nature-favoured places, brought 1s. 6d. a dozen. The products of the amateur garden were eagerly sought for at 12s.—("Meehan's Monthly.")

NATIONAL DAHLIA SOCIETY.

ANNUAL GENERAL MEETING.

THE annual meeting of this Society was held in the Hotel Windsor on Tuesday, under the presidency of Ed. Mawley, Esq. There was not a particularly large company present, and practically the whole of them were Dahlia specialists. Amongst those noticed were Messrs. R. Dean, J. Burrell, M. Seale, J. R. Tranter, A. Baxter, F. W. Fellowes, G. Gordon, H. A. Needs, C. E. Wilkins, W. Fife, S. Mortimer, G. Wyatt, J. T. West, and J. F. Hudson, Hon. Secretary. The last named read the notice convening the meeting, and scrutineers were selected for the ballot in the election of the officers of the Committee.

The official report proved the condition of affairs to be on the whole satisfactory, though, as with other of the special societies, the finances are not very flourishing. Reference was made to the decrease in the number of flowers exhibited at the Crystal Palace Show, which was accounted for by the extraordinary season through which the plants had passed.

In moving the adoption of the report and balance-sheet, both of which will be published in due course and forwarded to the members of the Society, Mr. Mawley said that, taking everything into consideration, the affairs were most satisfactory. At first glance, perhaps, the financial statement was not so good as it might be, but a study of the details, and a comparison with last year's returns, removed any doubt as to the flourishing condition of affairs. This was particularly the case when the two adverse Dahlia seasons just passed are borne in mind, as climatal fluctuations must of course militate more or less against the Society. Mr. Mawley made touching allusion to the death, in the prime of life, of his predecessor in the presidential chair, Mr. T. W. Girdlestone, and spoke of his services to the Dahlia Society and to horticulture generally. He said endeavour was being made to found a Girdlestone Memorial medal, and all friends of the deceased will wish the movement every success. In all respects, said the Chairman in conclusion, it was most desirable to keep abreast of the times, and in doing so, and propagating a love for Dahlias, increase in strength and prosperity year by year. After being seconded the motion was carried unanimously.

In subsequent remarks Mr. Mawley paid a tribute to the care and interest taken in the Society by Mr. J. F. Hudson, the Honorary Secretary, and congratulated the Society on having secured as Honorary Treasurer Mr. C. E. Wilkins of Swanley Junction, whose services will undoubtedly tend towards the Society's benefit. It was necessary, he pointed out, to reduce the prize money to a small extent, and this was done after a considerable discussion of the several classes in the schedule.

It was decided to hold one show only this year, and naturally everyone is hoping for a favourable season, which usually means a handsome exhibition. In addition to the several special prizes in the schedule, Mr. F. W. Fellowes suggested the inclusion of a class for nine varieties of Dahlias, grown and shown in pots, for which he would provide a £3 3s. cup, or the cash if preferred. This generous offer was accepted with thanks. A number of new bye-laws, mainly having relation to the affiliation of provincial societies, were proposed and carried; some other routine business concluded the meeting.

DECADENCE IN WALL TREES.

How forcibly does the wall of beautiful Pears, photographically represented on page 3 two weeks ago, contrast with the curious examples of trained trees which occupy so many garden walls in these modern days! Yet the present quick method of covering walls, the upper parts especially, has no lack of defenders, who like to regard themselves as advanced gardeners. "Advanced" they no doubt are in many things, but in the training of wall trees they are at the least a generation behind the old past masters in the art of gardening.

The modern go-aheads are in such a hurry that they have no time to train the branches well and at proper distances, so they flatten them against the wall as best they can. A few may be straight, but most of them will be the other way. By this so-called quickly-covering space system, which they think so good, we are almost certain to see, during the first two or three years, the strong branches where the weaker ought to be, and these latter in the rightful places of the strong. And then what? Just this: In a few more years the weaker lower branches dwindling away, and the stronger rising luxuriantly 3 or 4 feet above the top of the wall when the "summer pruning" (save the mark!) is done in or about September. If you have the temerity to whisper that the trees appear to have exalted notions, and do not seem to like humbling themselves by growing along the lower part of the wall, you will most likely be told "they always was so," and then you may listen for a delightful example of making a virtue of necessity. "Yes, they always was so; but they make fine room for Tomatoes. We have to go in for 'stuff' here, I can tell you."

Let us reflect a moment. Suppose Mr. Luckhurst, instead of selecting the right number of branches and knowing how to treat them for attaining his object, had allowed twice the number to extend as soon as they could after planting and let them go where they would the most easily; then imagine his filling the inevitable blanks on the lower part of the wall between them with Tomatoes, and nearly thirty years afterwards showing the result in a photograph. The wall must in this case have been a veritable eyesore, and not half of it clothed with fruitful wood; whereas now, as few will deny, it is strikingly ornamental—the branches and spurs uniform in vigour in every part and capable of bearing as many fruits as trees could carry. They are splendid examples of cultural skill carried out on intelligent lines and represent productiveness with economy.

The last word may startle some advocates of the express system who "run up" young Pear and other fruit tree branches too close by half as far as they will go, and "tack" them here and there with all due celerity for getting "ropes of fruit" in the least possible time. It is in reality an exhaustive practice. The crushed and crowded leaves are debilitated, and consequently the resources of the soil cannot be utilised by conversion into the first essentials of health and fruitfulness for storage in the stems and buds. Thus the bearing parts are quickly worn out, and have to be removed and others "laid in" to take their places. With fewer and better managed branches from the first, the leaves of these branches have twice the elaborative power of those which have had no chance of proper development.

No man who really understands the art of training trees into specimens of beauty and fruitfulness—for these desiderata are not in the least antagonistic—can inspect a number of well formed trees in any of our leading nurseries without a feeling of sadness creeping over him when he is compelled to think that many, if not the majority of the trees are destined to be spoiled. It is true that some nursery trees have more branches than they ought to have, as these are to be seen only 4 to 6 inches apart. They would be better if only half the number, and the first thing a man like Mr. Luckhurst would do would be to correct them. Unfortunately too many into whose hands such trees fall do nothing of the kind. They not only retain every branch its full length, and do not shorten the leader if 4 feet long, but as soon as they can "tack in" still more growths between the already too numerous mains, and thus lay the foundation for ruining the tree.

It is a simple fact that hundreds, aye! thousands of trees, which had been given a good start by skilled nurserymen, are subsequently ruined, and the wall space they were intended to cover ornamentally and profitably never will be covered by them. As a matter of fact more than half of the trees will, by the time they have been in their permanent position three or four years, be in such a deplorable state that even the nurseryman himself could not remodel them otherwise than by "stumping," or cutting the branches boldly back and forcing latent buds, if possible, and obtaining new growths from the base for a new start; but this desire he would find difficult to accomplish, because some of the lower and weaker branches would be so stunted and indurated, with weak blossom buds along their entire length and a terminal cluster at the extremity, that there would not be a bold wood

bud to cut back to with any confidence of its producing a strong "kind" growth for developing into a satisfactory branch; while on the upper part of the tree the branches would be four times more rampant than they ought to be in comparison with the stunted weaklings below them.

Two gardens are known at this moment to the writer in which a hundred young wall trees were planted four years ago. All the dwarf trees, and excellent trees they were, had leaders and side branches. The leaders have not been shortened yet. Some of them, that did not form terminal fruit buds for arresting their further progress, are at the top of the wall, and have thrown a side branch here and there of varying lengths and irregular distances, while most of the lower branches are so thin, lean, and stunted that they cannot do otherwise but dwindle away, and leave more room than before for the precious Tomatoes. "Good crop, isn't it?" observed one of the Tomato trainers, taking no notice of and making no reference to the smothered lower parts of the trees and the rampant unruly growths above.

The splendid Pear wall referred to—probably the finest of the kind in the kingdom—ought to prove an eye-opener to students of a neglected art. Let them look at the illustration on page 3 read the accompanying notes with care, and regard the lesson conveyed as a new year's gift not to be lightly disregarded. They will there see that the branches are the longest at the base, and decrease in length upwards; that every inch of a wall may be furnished with bearing wood instead of having the top-heavy trees that are so common. They will see that with the branches not less than a foot apart there is space for leaf-development, that sap-pressure is nicely balanced by the horizontal and vertical parts, and that the spurs are consequently equalised in strength; and moreover that trees thus formed require less time in attention to disbudding, pruning, cleansing, and occasionally refixing the branches than must be involved in conducting those operations when twice or thrice as many so-called branches have to be treated. Mr. Luckhurst has done a public service by his effective object lesson, and he can add to its value and the obligation of many readers by showing the working details for building up of such distinctly handsome, serviceable, and entirely meritorious trees.—A. N. O.

STAPELIA ASTERIAS.

Of all the members of the vegetable kingdom there is scarcely any which exceeds the *Stapelias* in quaintness of outline and floral extravagance. They are included in an exhibition section known as succulenti, and which also comprises the *Cactus*, the *Cereus*, the *House Leek* (*Sempervivum*), the *Crassula*, the *Echeveria*, the *Mesembryanthemum*, the *Opuntia*, and many others of high-sounding titles.

The Starfish *Stapelia*, or, as it is frequently designated, the Toad Flower, ought most certainly to have a place in all collections of plants whose owners desire to possess the curious as well as the beautiful. As may be seen in the illustration (fig. 10), the flower is very striking. The colour is a purple brown, mottled with yellowish white. *Stapelias*, like most succulenti, are not fastidious in the matter of soil, liking a sandy one, in which plenty of lime rubbish has been mixed to make it porous. They should be kept on a shelf well up to the light, and given very little water in the winter time, but abundance in the summer, sprinkling the plants, and not watering at the roots. On summer afternoons they should be shut up in a close moist atmosphere, when the odour emitted is peculiarly noticeable.

NOTES ON SEAKALE CULTURE.

THIS hardy perennial of our kitchen gardens is a native of the seaside, and is found growing on the shores of Britain. There are several varieties, the best of which is Lily White, which is chiefly esteemed because of the absence of the purple tip to the shoots. Beddard's Improved is another good variety, a cross between Lily White and the old purple variety, combining the best characteristics of both.

All the varieties may be raised from seed, though it is a slower method than planting roots. Seed should be sown in March, preparing the soil deeply previously. Sow in rows 18 inches apart, making the soil fine, and drawing drills with a hoe or rake. When the seedlings push through the soil hoe between the rows slightly to encourage growth, and thin the plants as soon as possible to 9 inches asunder. The following season lift the roots and replant, or what may be better, lift every other root and plant these in rows 18 inches to 2 feet apart, the roots being placed 15 inches asunder. The following season the roots will be strong enough to force, or the crowns may be covered

with pots in early spring to blanch the growth when it pushes, but it cannot be obtained so early by this method.

The plants will be stronger the third year, especially if growth is encouraged by the application of manures, such as guano 1 oz. per square yard applied in June. Salt is also beneficial at the rate of 1 oz. per square yard given between May and July.

Old roots are the best for lifting and forcing, and a portion of the stock may be treated in this way every year after the foliage has

18 inches, in rows $2\frac{1}{2}$ feet asunder. To maintain the stock this method should be followed each year.

The forcing of Seakale is carried out in various way, but heat, moisture, and darkness are essential. A hotbed is a suitable place, surrounding the roots well with soil and excluding light from the crowns. Planting the roots thickly in boxes or pots of soil and covering the crowns, then placing the receptacles in a moist and well heated structure, is a handy method of producing blanched leaf-

FIG. 10.—STAPELIA ASTERIAS.

died down in November. The thick, strong roots must be selected for forcing, cutting off the thin, thong-like roots and preserving them for future planting. These may be prepared for planting by cutting them into lengths of 6 inches, cutting the upper part transversely and the lower part slantingly, so as to distinguish the crown end. Lay the roots in sand or ashes until March, when they can be planted. By that time the upper part of the roots will have produced a ring of growth, or little buds. When the roots are planted the buds will advance, but eventually only allow the strongest to remain. The distance between the roots may be, in good soil,

stalks for early use. To maintain the supply introduce roots into heat in successive batches. Later in the season a good supply of blanched produce may be secured by covering the roots with Seakale pots or tubs, which are handy by reason of their having movable covers or lids.

Seakale is often obtained early by forcing the roots where they are growing. For doing this the crowns must be covered with pots having movable lids. Fresh growth from the root is desirable, and this can be had by thinning out the buds which are produced.—E. BARROW.

BEGONIA SOCOTRANA.

ABOUT twenty years ago this handsome species was introduced to Kew from the island of Socotra by Dr. Balfour, and a few years later it was put into commerce by Messrs. Veitch. On first flowering it was found to possess the qualities of a first-rate garden plant, and hopes were also entertained that it would prove useful to the hybridist. That it has fulfilled the promises of its early days is quite evident, for besides being a most useful and showy winter flowering plant, it is one of the parents of the new race of winter flowering Begonias typified by *B. Gloire de Lorraine*.

In general appearance it differs from most other species. It is included in the tuberous section, but differs from other members by making a large number of small bulbils instead of one single tuber. The leaves also differ from those of other species by being quite round, with a cup-shaped depression in the centre. From each bulbil a stoutish stem is made a few inches high, on which from four to six of the handsome, bright green leaves—which are from 4 to 6 inches across—are borne. The flowers are produced in medium-sized, loose trusses well above the leaves; they are bright rosy red, and 2 inches across.

Unlike other species, this requires resting during summer, and should be kept perfectly dry from the time the leaves fall until August. At the beginning of this month the tubers should be divided, and potted several together in 3-inch pots in a mixture of loam, leaf soil, and peat in equal proportions, with a fair quantity of sand added. They should be placed in a house having a minimum temperature of 55°, and little or no water given until growth has commenced. After leaves appear the plants should be grown quickly without a check, potting when necessary until they are in 6-inch pots. When the pots are filled with roots liquid manure should be given. Under this method big plants should be obtained, which will flower from the end of November onwards for at least two months.—W. D.

HARDY VINES FOR THE OPEN.

I WISH to thank the various correspondents for their interesting notes on outdoor Vines, on pages 468, 496, 520, and 541. I am particularly obliged to "F. S., Dumbarton," for giving his experience so far north as Scotland, and hope he will favour us with further notes this year; also to Mr. H. M. Tod for the list of sorts he has found to ripen early, and those that are uncertain to ripen. The suggestion that not only the unripe fruit, but the superfluous green growth of Vines, with sugar added, will make wine equal to ripe fruit is worth knowing, as there are always an abundance of surplus growth. There are various ways in which unripe fruit can be used instead of wasted. This and the thinnings of Grapes can be utilised for tarts or simply stewed, but the best way of using the fruit at any stage, particularly by those who have only a small or a moderate quantity, is in the form of Green Grape jelly, which is very good.

Mr. Tod mentions American Brandt. It would seem this variety is fairly satisfactory, but are there not several of the American varieties which would succeed in our climate? Perhaps some of the readers of "our Journal" will give their experience with these.

It would be most interesting, and in all probability useful, to set about cross-breeding, so as to produce finer sorts and earlier ripening varieties than any we now possess. This has already been brought about with other fruits, and splendid results have been achieved. Only a few days ago I was told by an ex-soldier that he saw in the cold parts of Abyssinia splendid large Grapes growing in the open, of good quality. They were simply planted on hillocks, the branches resting on the ground. Can anyone give any information on this variety?

"Wanderer" mentions Reine Olga Grape as being easy to grow in the open. Will someone kindly give their experience and any information of this Grape, or any other hardy variety they have found a success?

Enclosed I send a newspaper cutting, showing that vineyards were established in England before the Norman conquest, and that Lincoln was one of the places where they were grown—presumably on the southern slope of the hill, where we now have a street called "Vine Street."—W. B., Lincoln.

[The "cutting" referred to is from the "Globe"—a long narrative of old English vineyards, and concludes as follows:—"Old Vines still adorn the south walls and sunny gables of many cottages and farm-houses in the southern counties of England, and in favourable seasons a fair yield of Grapes may be obtained. These wall Vines are so picturesque that one would fain hope the day is far distant when they will be superseded by more showy creepers. But to attempt to revive the systematic cultivation of the Grape, with the view of producing wine which should compete in any degree with the growths of foreign vineyards, would be perfectly hopeless. An isolated experiment, conducted with unwearying labour and pains, like that of the Marquis of Bute, when circumstances are favourable, and when profit is no object, may meet with some degree of success. But from a commercial point of view such efforts are practically foredoomed to failure. English wines played a useful part in the past, and doubtless satisfied palates imperfectly educated, and not too fastidious; but beverages which, in the expressive language of the old chronicler, 'twisted the mouths of the drinkers,' would have few attractions for modern consumers."]

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ANNUAL GENERAL MEETING.

THE annual general meeting of this estimable Institution which was held under the presidency of Mr. Harry J. Veitch at Simpson's Hotel on Friday last, did not bring together a very large gathering. Amongst the best known horticulturists present were Dr. Maxwell T. Masters, and Messrs. G. Monro, W. Roupell, W. Denning, J. Fraser, H. J. Cutbush, G. Wythes, J. H. Veitch, J. Willard, A. G. Monro, T. Manning, and Ranger Johnson. After the Secretary had read the minutes of the previous annual meeting, Mr. Veitch rose and put the following proposition, which was adopted without a dissentient voice:—

"That this general meeting of subscribers of the Gardeners' Royal Benevolent Institution desires to place on record its deep sense of the very grievous loss sustained by the Institution through the death of its President, the late Duke of Westminster. It also gratefully records the great interest always evinced by his Grace in the well being of the Institution and the liberality he continually showed during the twenty-one years that he occupied the office of President."

The Secretary then read the report and balance-sheet as follows:—

REPORT OF COMMITTEE FOR 1899.

The Committee in submitting their annual report for the year 1899 again have the great satisfaction of congratulating the members and subscribers on the prosperous condition of the Institution and the marked progress which happily has been made during the year, not only in respect of its financial status, but also in dispensing its assistance to a greater number of old and worthy people whose circumstances and necessities have obliged them to seek its aid.

At the beginning of the year 174 pensioners—ninety-five men and seventy-nine widows—were receiving £20 and £16 a year respectively, entailing an annual liability of £3160. Of this number during the year nine men and one widow have passed away, while another man whose circumstances have changed has voluntarily relinquished his pension; thus leaving a total number of 163 on the funds at the close of the year. The Committee propose to increase this number, and recommend that sixteen pensioners be added—ten by resolution under power conferred by Rule iii. 5, and the remaining six by the votes of members and subscribers, giving a total number of 178 pensioners, being four more than the number on the corresponding date last year. The number of beneficiaries will then be larger than at any period of the Institution's past history; and whilst keenly alive to the increased liabilities necessarily to be incurred, the Committee are also confident they may rely upon the continued and increased support of the friends of the Institution.

The Committee have to report that the anniversary festival dinner in aid of the funds, under the presidency of the Right Hon. the Earl of Derby, K.G., P.C., proved most successful, and they desire to place on record their grateful thanks to his lordship for his able and effective advocacy of the claims of the Institution, which resulted in such a substantial addition to the funds, as well as for his lordship's own generous contribution. In reply to the vote of thanks tendered by the Committee, Lord Derby was pleased to send the following communication:—

Derby House, St. James's Square, W.

July 3rd, 1899.

My Dear Sir,—I thank you for your letter of this date conveying the kindly message sent by your Committee with reference to the festival dinner of the Gardeners' Royal Benevolent Institution on the 28th ult. I am very glad to learn the result of the dinner is considered to have been satisfactory. For my own part I certainly say that I am very happy to have attended so pleasant a gathering, and that I am sincerely grateful for the assistance and support which I received as your Chairman from all present, and especially from the Treasurer and yourself.—I remain, my dear Sir, yours very faithfully,

(Signed) DERBY.

GEORGE J. INGRAM, Esq.

The Committee take this opportunity of gratefully acknowledging their indebtedness to the Stewards, donors of flowers, and the horticultural press, and to others who in any way contributed to the success of the anniversary. They likewise tender their best thanks to the Honorary Secretaries of the several auxiliaries for their kind services, and also to other friends throughout the country, who, by arranging concerts, flower stalls, opening their gardens, and in other ways have so materially assisted the Institution. The Committee are glad to announce the formation of an auxiliary at Reading under the presidency of Charles E. Keyser, Esq., and the treasurership of Arthur W. Sutton, Esq., which they feel will be of great advantage in diffusing fuller information of the Institution and creating a wider interest in its work in that district. Their thanks are specially due to Mr. Sutton, to whose influence and indefatigable exertions the establishment of the branch is due.

To the Messrs. N. M. Rothschild & Sons, who have again contributed their generous annual gift of £105; to the anonymous donor who left four £5 notes at the office "In Memory of Robert Fortune;" and to other friends too numerous to mention who have so generously given to the funds, the Committee offer their most grateful thanks.

The Committee are glad to be able to announce that the additional sum required to complete the "Victorian Era Fund" has been obtained, the total amount thus raised for this fund being £5000, which has been invested in Great Western Railway 5 per Cent. Consolidated Stock, the interest derived therefrom, it may again be stated, being devoted exclusively to the benefit of unsuccessful candidates who have been subscribers to the Institution.

During the year the following persons have benefited from this Fund, and the grateful letters which have been received from them show how much the help was needed, and how keenly it was appreciated:—David Benning, £8; Andrew Bryan, £10; Sarah Bullen, £5; George Chitty, £10; Jane R. Edwards, £10; Thomas Evans, £5; John Gibbons, £10; William Gould, £2; Elizabeth Hackwell, £8; Samuel Mills, £6; Lucy Mitchell, £7; Francis Nixon, £10; William Thomas, £2; Isabella Watt, £10; George Wills, £10. Two of the above have since passed away, and the timely aid thus afforded to them was doubly acceptable.

The Committee have also to announce that the Good Samaritan Fund, which was inaugurated at the commencement of the year, has received contributions to the amount of £520 17s. Of this amount £520 has been invested in 2½ per cent. consols. The object of this Fund is to grant temporary relief in urgent cases of trouble and distress. The Committee therefore very earnestly commend the Fund to the practical sympathy and support of their friends.

In concluding their report, the Committee have to refer with great regret to the losses the Institution has sustained during the past year by the death of many supporters, amongst whom they have to record with deep sorrow that of their valued and generous President, the Duke of Westminster. His Grace had occupied the office of President for a period of twenty-one years, and throughout the whole of that time had evinced a warm interest in its work, and was ever ready to afford it his powerful aid, both by his advice and practical support. His Grace will be greatly missed, and the Committee deeply deplore his decease. They have also to refer to the death of their old friend and colleague Mr. John Lee. He has been connected with the Institution for sixty years, and as Chairman of Committee and Trustee for many years had taken an active interest in its affairs. He died at the ripe old age of ninety-six, beloved by everyone, and warmly appreciated for his devoted services to the Institution. The Committee have likewise to record their great regret at the death of their colleague Mr. M. Dunn of Dalkeith and they desire to take this opportunity of expressing their high appreciation of his efforts on behalf of the Institution.

These many losses have created gaps in the ranks of the supporters of the Institution which it will be difficult to fill, and the Committee therefore plead the more earnestly for new friends and helpers to take the places of those who have passed away.

Having audited the accounts, we certify the same to be correct; the books are well and accurately kept. We have also satisfied ourselves that the securities of the invested funds are in the hands of the bankers, through whom the dividends are remitted.

THOMAS SWIFT,
THOMAS MANNING, } Auditors.
J. WILLARD,

9th January, 1900.

Mr. Veitch in moving the adoption of the report and balance sheet was as usual brief and very much to the point. He considered the affairs of the Institution as shown in the official statements to be in a most satisfactory state, indeed he said the year 1899 was to be characterised as the most successful in the annals of the Society. He referred to the completion of the Victorian Era Fund, and also to the fact that the Good Samaritan Fund, which was first mooted a year ago, was already firmly established, and did not doubt but that, as in the case of the first-named fund, it would prove of inestimable value in giving temporary relief to necessitous cases. He then moved:

"That the report of the Committee, together with the statement of accounts, as audited and certified, for the past year now read be received and adopted, and that the best thanks of this meeting be presented to the Committee for their able management of the affairs of the Institution for the past year." Dr. Masters seconded the proposition, which was carried unanimously.

The following elections of officers was promptly proceeded with, and in no case was there a single objection raised.

"That Mr. Harry J. Veitch be re-elected Treasurer, and that the best thanks of this meeting be presented to him for his invaluable services to the Institution for the past year." Proposed by Mr. W. Denning, seconded by Mr. Osborn.

"That Mr. George J. Ingram be re-elected Secretary." Proposed by Mr. Geo. Monro, seconded by Mr. Geo. Wythes.

"That Messrs. W. Y. Baker, J. Hudson, S. M. Segar, H. Turner, and H. Tillman, who retire by rotation, be re-elected members of Committee, and that Messrs. John A. Laing and John Jennings be elected members of Committee in the places of Mr. John Laing, who retires, and Mr. M. Dunn, deceased." Proposed by Mr. H. J. Cutbush, seconded by Mr. W. Roupell.

"That Messrs. Thomas Manning, Thomas Swift, and Jesse Willard be re-elected Auditors for the ensuing year, and that the best thanks of this meeting be presented to them for their kind services during the past year." Proposed by Mr. J. Hill White, Worcester; seconded by Mr. W. Denning.

"That Messrs. W. F. Besté, W. Crane, H. Higgins, W. Johnson, and R. A. Jack be re-elected Arbitrators for the ensuing year." Proposed by Mr. A. J. Baker, seconded by Mr. W. Ieeton.

"That William Armstrong, Andrew Bryan, Thomas Chapman, George Chitty, William Hole, Francis Nixon, Samuel Smalley, Richard H. Smith, Joseph Willis, John Wilson, whose cases have been investigated and appear to be deserving and necessitous, be placed on the pension list without election under the power conferred by rule iii, 5." Proposed by Mr. J. H. Veitch, seconded by Mr. S. Osborn.

"That Mr. Edwin G. Monro and Mr. Thomas Manning be elected scrutineers, with full power to decide all questions arising out of voting papers." Proposed by Mr. W. Roupell, seconded by Mr. W. Ieeton.

DECLARATION OF THE POLL.

Shortly before five o'clock the scrutineers, Messrs. Thos. Manning and A. G. Monro, returned to declare the result of the poll, which was as follows:—Isaac Page, 4519; Lucy Mitchell, 4282; Jane R. Edwards, 3986; Thomas Evans, 3383; William Thomas, 3228; Isabella Watt, 2845. William B. Glasscock received 3346 votes and would therefore have become a recipient of the pension but for the fact that since the list was published his circumstances had so changed as to render pecuniary aid from the Institution unnecessary. It was mentioned as remarkable that since the list had been ready four candidates had passed to their eternal rest. The scrutineers announced as a matter for congratulation that only thirty-seven votes were wasted this year through papers not being signed, as against nearly 600 last year.

Votes of thanks to the Chairman and Messrs. Manning and Monro brought the proceedings to a close.

THE ANNUAL FRIENDLY SUPPER.

There is probably no gathering of horticulturists, at any rate within the metropolitan area, that better deserves the title of "Friendly" than this meeting of the supporters and friends of the Gardeners' Royal Benevolent Institution. It would, we are perfectly convinced, be a difficult, even if not an impossible, task to find another charitable institution that runs its course on a sounder basis. In investigating its affairs by the aid of reports and balance-sheets and from information gathered in conversation with the best of secretaries, Mr. G. J. Ingram, it is promptly found that the subscriptions and donations are not sought for the maintenance of ornate buildings and ornamental officials, but for the gardeners of Great Britain and Ireland. The money comes and the money goes, not perhaps with the regularity of the ebb and flow of the tides, but steadily and persistently, and with the exception of an infinitesimal percentage for office expenses, every halfpenny goes to the gardeners and their widows in their hour of need.

Having in view this incontrovertible fact that a committee of earnest business men manage the affairs of the Society for the benefit of gardeners, it might naturally be asked, "Do the gardeners give the Institution the pecuniary support it deserves?" Many times has a negative answer been recorded; but it requires qualification. There are gardeners and gardeners, and, as Mr. Moss observed, they are not all millionaires. Many there are who could subscribe and do not. This is not from feelings averse to the work of the Society, but rather from an unfortunate apathy which we anticipate the ever increasing auxiliaries will eventually remove. Look, however, for a moment on the other side of the slate, and there will be found a large majority whose remuneration for intelligent labour is decidedly limited, and who have many pressing home calls. Should these people be excluded from the benefits of the charity? Mr. Veitch, in founding the Good Samaritan Fund, replies with an emphatic No. And he is right—it is the man's misfortune, and not his fault in this case.

But we are digressing and must return to the leadership of Mr. Arnold Moss, who occupied the chair on this occasion in place of Mr. Bilney of Weybridge, whose presence at home was enforced by the influenza fiend. Mr. Moss, in dryly humorous terms, referred to the report and the balance sheet, and kept the half hundred participators in the supper in a constant roar of happy laughter ere settling down to serious business. When this stage was reached he referred to the regrettable absence of Mr. Bilney, and also to the death of the President of the Institution—his Grace the Duke of Westminster. He spoke of the flourishing condition of the Society, and hoped the prosperity would be maintained in the future. He alluded in most complimentary terms to the good work of gardeners, whose labours were not always of the easiest or of the pleasantest, and the tone of his remarks proved his familiarity with them and their work, and the high esteem in which he held them. He asked all present to drink to the increased prosperity of the Gardeners' Royal Benevolent Institution, and there was no traitor in the camp.

This toast has for years past been supported by Mr. Harry Veitch, but on this occasion a change was necessary, as this gentleman was precluded from being present on account of his almost immediate departure (with Mrs. Veitch) on a tour to the Holy Land. The task was therefore delegated to Mr. George Monro, and he handled his duties most capably. He spoke of the amounts subscribed and of the number of people now enjoying the benefits of the Society, and paid a thoroughly deserved tribute to Mr. Veitch when adverting to the Victorian Era and Good Samaritan Funds. Reference was also made to the possibility of the war now unhappily in progress in South Africa affecting the returns during the present year, and exhorted all and sundry absent as well as present to do their utmost to keep the Institution in the foreground, and by annual subscriptions help materially towards its permanent prosperity. Mr. Monro's remarks were terse and well chosen, and it is sincerely to be hoped that they will bear abundant fruit.

Mr. Owen Thomas, whose interest in the Institution is second to none, proposed the toast of "Our Country Friends and Supporters," and, as is ever his motto, urged gardeners to increase their support to a Society that was so entirely beneficial to the craft. He referred to the admirable work of the auxiliaries, and looked for their extension. Mr. George Bunyard responded. Other toasts were proposed and received in the most excellent spirit, ere a most enjoyable meeting was brought to a close.

THE ATMOSPHERE, AND THE ATMOSPHERIC FOOD OF PLANTS.

(Concluded from page 31.)

It is from this small proportion of carbonic acid gas (4 gallons to 10,000 gallons) in the air that plants get the carbon (charcoal) that forms so large a part of their solid substance. The way in which they take it in is something like this:—

The green colour of green leaves is due to very small and very numerous green granules contained in cells in the interior of the leaf. This green substance is called chlorophyll. These same cells contain also the ever-moving living liquid jelly-like protoplasm, which has been described as the life-substance of the plant. Through the outermost thin transparent skin, or pellicle, covering the leaf there are numerous microscopic pores, or openings or mouths, called stomata or stomates, communicating with these green cells. Now, through these stomata the carbonic acid gas of the air reaches the chlorophyll in these cells; and, under the action of the sunlight, the chlorophyll (in the presence of moisture and protoplasm) breaks up the carbonic acid, causing it to give up the whole or part of its oxygen, which then returns to the atmosphere, and building up the carbon and the remainder of the oxygen into starch, dextrine, all the sugars, the gums, and cellulose or woody fibre, and other plant tissues. Water, drawn from the soil by the roots and passed up into the stem and leaves, is necessary for these tissue-building vital processes. Indeed, all the substances just named—starch, sugars, &c.—contain nothing but carbon combined with the elements of water (hydrogen and oxygen). The transformations can be expressed by the following chemical equations, in which CO₂ always means carbonic acid gas, H₂O water, C₆H₁₀O₅ starch, dextrine, gum, and woody fibre or cellulose, C₆H₁₂O₆ fruit sugar, honey, &c., and C₁₂H₂₂O₁₁ cane sugar. The equations would then be—

—meaning that 264 lbs. of carbonic acid and 90 lbs. of water would make 162 lbs. of starch or woody fibre, and 192 lbs. of oxygen gas.

—meaning that 264 lbs. of carbonic acid and 108 lbs. of water would make 180 lbs. of fruit sugar and 192 lbs. of oxygen gas.

—meaning that 528 lbs. of carbonic acid and 198 lbs. of water would make 342 lbs. of cane sugar and 384 lbs. of oxygen gas.

(In all chemical equations C counts for 12 parts of carbon, O for 16 parts of oxygen, and H for 1 part of hydrogen.)

In the dark the green chlorophyll has not the power of thus breaking up carbonic acid and water and constructing the plant-substances named above from the materials. There are therefore four conditions absolutely necessary for this plant-building business:—

- 1, Carbonic acid gas in the air;
- 2, Green chlorophyll granules in the living plant;
- 3, Moisture from the soil;
- 4, Exposure to the sunlight.

The part that light plays in assimilation of carbon and the growth of plants is apt to be overlooked. It is just as necessary as the carbonic acid of the air or the chlorophyll of the green cells. The disastrous effects of insufficient exposure to light are readily observed. We have an instance of it in the straggling, stunted, starved condition of the trees in the middle of an overcrowded forest or patch of bush. The weaklings there, shadowed by their taller and more umbrageous neighbours, begin to lag from the insufficiency of the light that reaches them. One often sees an unlucky plant of this kind spending all its available nourishment in stretching up a tall, slim, scraggy stem, carrying its leaves as high as possible to reach the open air and get a glimpse of the sun, turning now this way, now that, in search of a patch of light.

The abundance of light and their free and full exposure to it are partly the reason why the individual plants of a thinly sown crop (other things being equal) are more vigorous than those of a dense crop, because they have fewer neighbours to shadow them. Everyone has observed the meagre growth of the grass grown in the shadow of a lofty belt of leafy trees. This is mainly due to the lack of plant food, but partly also to the want of light. Also note the vigorous rush-up, brightening green colour, and rapid growth of the young grass that has just been relieved of the overshadowing crop of Barley or Oats, among which it was previously struggling to maintain a precarious existence.

The rapid growth of Barley and Rye, and even Wheat, in the Orkneys, Norway, Sweden, and in cold Siberia as far north as 66° and 70° of latitude in the long, almost continuous summer days has been attributed partly to the same cause—namely, the continuous exposure to sunlight which the plants enjoy in the short summer of these northern latitudes.

We have another instance of the influence of light in the well-known superior fertility of the sunny slope on which the plants are exposed to the direct perpendicular rays of the sun; while on the adverse slope (quite irrespective of the cold) they struggle on in a meagre, hopeless way, feeling the solar influences for shorter periods, and with less directness in his beams.

CUSCUTA CHILENSIS.

THE profusion in which the very pretty fragrant flowers are borne over the whole of this leafless plant cannot but excite admiration, nor can its habit of growth and the inevitable consequence of its vigour, when growing on many of its foster plants, occasion any but feelings of wonderment. It has been cultivated under the erroneous name of *C. chinensis*, a species of only annual duration, whereas the one under notice is indisputably a perennial, and it may be easily inferred that the confusion as to names has arisen simply through an inadvertent clerical error. Many *Cuscutas* have been introduced from various countries, and these are more numerous than may be generally imagined, more than thirty being enumerated in Steudel's "Nomenclator Botanicus," and this does not include the well-known indigenous Dodder.

It has been stated that Daddies grow only upon herbaceous plants and the smaller shrubs, yet Shakespeare employed the term "doddered" to the Oak, from which it has been assumed that the word formerly was not only applied to parasites generally, but figuratively, in describing trunks of trees clad with vegetation. As expressed by its name, *C. chilensis* is a native of South America, and it so much resembles the Peruvian *Cuscuta*, *C. odorata*, that it is very probable the question as to whether they are not identical has yet to be determined. Those who have had an opportunity of witnessing its wonderful growth and effect when cultivated under favourable conditions in this country may be able to form some idea of the character of this plant when growing in wild luxuriance on some of the most fitting of its foster plants, and readily realise the regard in which it is held by the Spanish Creoles, who have applied to it the popular name of *Cabellos de Angel* (Angel's Hair). Whether this exotic parasite, which appears to have been introduced from Chili in the year 1821, is capable of being acclimatised is uncertain, but should it prove to be so it would be difficult to imagine a more undesirable plant to introduce amongst some of our field crops. It certainly is sufficiently hardy to withstand 3° or 4° of frost, but flowering as it does rather late in summer, when growing in this climate out of doors, there does exist for agriculturists the assurance that it would only, in very exceptional seasons, ripen its seeds; were it otherwise they might fairly be appalled.

When observed in a small state, growing on some suitable soft-wooded plant to which it has been allowed to attach itself for preserving it through the winter months under glass, there is nothing particularly striking in its appearance, and under such a condition there is relatively nothing to suggest the extraordinary spectacle it will present when its growth is fully developed. It is only necessary to have an established piece, even though it be growing on such a plant as would ordinarily occupy a 5-inch flower pot, and so soon as the late spring frosts are over to remove it to a suitable place, to demonstrate its amazing characteristics.

Supposing it to have been placed close to a dwarf Ivy-clad wall, sheltered and shaded by deciduous and evergreen trees of a large growth, here and there a Lilac, a Flowering Currant, or Box tree, and then large Elders, the latter perchance draped with that always picturesque British climber, Traveller's Joy (*Clematis Vitalba*), in such a place as this the Chilean *Cuscuta* would soon manifest its prodigious growth. Attaching itself to the nearest plant, herbaceous or otherwise, its unde stems presently embrace those of others within reach one after the other, in snake-like coils, sometimes singly, but not unfrequently in twos and threes, and in its progress completely fixing itself by penetrating their epidermis with its root-like tubercles. The more it becomes established the more vigorously it grows, sending out strong thong-like lateral shoots, in some cases several feet in length, and these soon take possession of the branches of surrounding shrubs and trees for a distance as much as 15 feet from the spot where it was originally placed.

At the same time a portion of the parasite will be luxuriating amongst the Ivy, elevating itself above the branches in the most fantastic fashion, some of the more thread-like stems coiling themselves round the larger ones, and together eventually forming an inextricable densely matted mass of as curious an example of vegetation as it is possible to conceive. It is, perhaps, on Ivy that it best displays itself, so incredibly luxuriant does it become as to almost conceal it, and it is from a spray of this plant that the accompanying illustration (fig. 11) has been produced. As has been stated, it does not commence flowering until somewhat late in the summer, but then its delicate diaphanous flowers are produced in clusters over the whole of the plant in the greatest abundance. These are clear white faintly spotted with a purplish hue, and emit a fragrance suggestive of both Hoya and Heliotrope.

The rather uncommon species of *Cuscuta* deservedly claims attention as worthy of cultivation, not only on account of its being so free flowering, but as well of the fact that there are very few flowers that can vie with it for retaining a fresh appearance when cut and placed in water, more especially if a portion of its foster plant be cut with it, in which case it will remain a pretty object for as much as three or four weeks. In combination with other flowers for table decorations it can be made to present quite a unique appearance, and for this purpose its value cannot be over-estimated.—S. S.

THE WANDERINGS OF MR. PETER BARR, V.M.H.

A FEW weeks ago (page 494, December 7th, 1899), in connection with the subject of Irises, we made reference to a letter from Mr. Peter Barr, in which, among other things, he described a visit to the Iris fields in Japan. The letter was alluded to as a remarkable one, as penned by a writer seventy-four years of age, because it contained 3000 words on three sheets of note paper. That was a slight error. Four sheets were used, and they contain over 6000 words; size of sheets 8½ by 5½ inches. We know of writers who could inscribe with admirable clearness more matter into the same space, but they are not septuagenarians, nor could they describe similar experience. The narration is not limited to gardening by a very long way, but is little,

FIG. 11.—CUSCUTA CHILENSIS.

if any, the less interesting on that account. It is just a free and easy description of scenes and situations, also men and women that were met with by a close observer with a good memory, and who can record without much trouble his impressions, while not being altogether lacking in the critical faculty. Though not written for the purpose of publication, we have no hesitation in inserting a considerable portion, as a change from ordinary literary fare, and commence with one of the sheets of the chatty communication.

ON THE WAY AND IN THE U.S.A.

I fear you will think me a strange fellow after all your kindness and your very friendly letter of April 4th, 1898, not to have written to you sooner. Should you ever leave off editing a paper and take to travelling and give yourself up to pleasure and relaxation you will find out how difficult it is to find time to do correspondence, especially if your feet be directed to the United States; and as far as my wanderings have yet led me, the U.S.A. is the one country for a man to travel in who desires to study men, manners, and the development of the human race.

Before leaving England (the British Isles) I thought it best after

saying adieu to my Scottish friends to visit Ireland and see how matters stood, in case I should meet an Irishman at the corner of every street in every town in the U.S.A. holding forth on the grievances of "Ould Ireland," so that I should from personal knowledge be able to say, "Pat, shut up, if your love for Ireland is as great as your hatred of the Saxon; the Irish farmer is in a better position at present than the same class in England and Scotland." I am glad to say I met none in my travels who had an evil word to say about England; but I actually met with parties who regretted that the U.S.A. and Great Britain were not one and the same country. The feeling was universally favourable to a close alliance of the States and Britain.

I sent you from time to time newspapers, showing you what an active class of men the American interviewer presents to the world; these papers were intended as an apology for a letter. To show you how my correspondence stood when I reached Japan, I was somewhere about 100 letters in arrears, and if you wonder what 100 long letters mean, take this one as a sample. I arranged the letters in alphabetical order, and am getting to the end of the list, but as each mail brought some new correspondence to be attended to a portion of my time in Japan has been taken up letter writing.

Now for my tour. I reached Boston, Mass., U.S.A., April 18th, after seeing the big storm in mid-ocean, when the water was tumbling about in great masses as large as the twenty-storied houses of the States. I did not see the typical storm represented on canvas and described in books of the great crested waves rolling one after the other and the good ship "Seythia" climbing the one roller with the bow high out of the water and descending the other side with the stern up in the air and then into the trough of the sea, getting ready for the next mount, but we sailed in the midst of three great lumps of water; any one of them falling on the deck would have given us a watery grave.

Arriving at Boston Harbour, the first demand made was, How much money have you? The next was 2 dollars for a short ride in a cab to my hotel. My face washed and clothes put in visiting order, I made my first call on a dry goods man, who sent one of his young men to show me the lions of Boston. The first was the Monument on a "humplock" of soil, whence the men of the Revolution had repulsed the British forces. After that I was able to see more quietly the philanthropy that permeates the monied men of Boston. Hospitals all about, and little hospitals sufficiently numerous to take in accident patients, attend to immediate wants, and then convey to a larger hospital.

The next day was Patriot Day, when there is a great gathering to commemorate the triumph of the Revolution. The day was threatening, so I turned my attention to nurseries, and managed to do two, but was not impressed by either; then I called on a Rose grower in a private place, and found some excellent work in the production of Roses. After this I saw some other sights and then settled down to make a study of the schools and find out through them the success of the U.S.A.

Their educational system is older than ours, but developments of an important nature commenced about the time we established Board Schools, and they have kept well ahead of Europe. One advantage the schools have, they are not hampered by sectarian or any other influences of a partisan character such as seem to prevail in the older countries of the world. I spent a good part of three weeks amongst the schools from the lowest down where the strangers from Russia, Poland, and Hungary are at once taken hold of and taught English and thus turned into citizens, up to the training schools for teachers. The work throughout is splendid. One thing strikes a stranger — the almost total absence of those who twang their nasal language in your ear. Much of this you hear in London Yankees is put on. The schoolmaster is destroying this as he is putting the h's in their right place in England and clearing away the sweet drawl of Edinburgh and the rough tone of Glasgow.

Having finished my work in Boston I worked down towards New York, taking the towns on my way and looking up friends, and the man near Middleton who had invested his money in catching gold from the sea. The thing came about in this way. A preacher conceived the idea that to tax people to listen to him was not gospel, so he trusted to faith and his congregation, and the congregation not averse, let the preacher live in faith, and as this did not fill his stomach nor cover his back, he bethought how he could raise the wind, and attending a lecture on one occasion the lecturer said there was gold floating in the sea; then came the question how to catch this much-needed article. He thought out a plan, put it in motion by securing a foreshore, letting the sea water in and then closing it up, so that in the return passage it had to pass through his machine, with the result he caught gold and silver. Then he approached a well-to-do Scandinavian nurseryman who advanced 2000 dols., and the work went on merrily; more money was advanced, till like other benenolent speculators he thought the public should share the loss and gain, if any. I think the London papers told the rest of the story in 1898.

I reached New York, found Mr. Leonard Barron and Mr. Withers on American "Gardening"; both showed me great kindness. I met other friends, and then went off to Rathmore. Here my good luck continued with me, and an English gardener took me about, and in their great park is a fine monument to Sir William Wallace, raised by a patriotic

Scotchman. My next town was Washington, D.C., here I spent most of my time in the State agricultural department, giving and receiving information. A mighty work is going on in this department, the head of it, Secretary Wilson, is a Scotchman. There are professors to look into and study diseases of plants and injurious insects, collecting together every kind of produce imported into the States to see if the same cannot be grown in one or other of the States of the Union. I entered every branch to see what was being done for the good of the country. If you do not get the annual report you should apply for it. Every citizen of the U.S.A. is entitled to a copy if they want it, but they give freely to anyone out of the States, and I should not be surprised if one is at King Street for me, if so you can have the loan of it.

As a country Great Britain is in the tail end of all countries educationally, even Japan. We leave all to private enterprise, and only in the building of big battle ships does the Government take the initiative. It is a great pity that a million or two otherwise spent were not devoted to bringing us in line with the work done for the tillers of the soil in the U.S.A.

I then went to Pittsburg to see Mr. Falconer, superintendent of Sepley Park, and formerly on the horticultural press of London, spent some days with him, and visited Andrew Carnegie's steel works, then the Quaker city (Philadelphia), but saw none I could recognise as Quakers; the Penn hat, the stand-up collar, and the draped coat had all gone. Here I found a lot of good growers, Mr. Drew's nursery is a big concern, and a great work goes on amongst out-of-door Water Lilies and Victoria regia Tuckeri. Returning to New York Mr. Hicks Arnold considered my not seeing the Yellowstone Park would be a mistake, so off I started direct, a long railway journey, running day and night on a quick train. No one can form any idea of a railway journey till he gets a taste of it in crossing the American continent. From the time of leaving the train to the time I was again back to New York was about eighteen days.

Next follows a description of the Park and a drive with one of the wives of a Mormon Bishop.

JUDGING MELONS.

In referring to the remarks of Mr. Temple, on page 565, respecting the judging of Melons, I feel assured that to abolish the practice of cutting the fruits when in competition to ascertain their chief merit — viz, flavour, would not only cause dissatisfaction among the judges, but would also be a great injustice to exhibitors. It is practically impossible for any judge to arrive at a correct decision as regards the quality of a Melon without tasting it. There are numbers of fruits staged at horticultural exhibitions from time to time which, so far as appearance goes, are *par excellence*, being perfect in shape, beautifully netted, and highly coloured, but deficient in flavour. It cannot be denied that the aroma is a fair criterion as to flavour, but even this sometimes is not reliable.

I am inclined to think that the Fruit Committee of the R.H.S. would not favour the abolition of cutting Melons when submitted for their approval, as flavour and depth of flesh are the chief points. These gentlemen knowing what constitutes a good Melon regard size, shape, netting, and colour, which go to make up the external quite of secondary importance, and only first-class varieties find favour and meet with recognition. We all believe, do we not, in the old saying that the proof of the pudding is in the eating? and it is equally applicable to the Melon.—J. BARKHAM, Longford House, Haven Street, I.W.

I KNEW well what I was writing about when making a few remarks on, what has been so often discussed, the judging of Melons by the "non-cutting" system, I therefore did not unconsciously emphasise the need of cutting the fruit to ascertain its condition. I never could at any time tell what the flavour of a Melon was from any external signs. Neither, scent, colour, form, nor the absence of these points gives indications as to the quality of the fruit. "K." (page 8) may rest assured that I am not at variance with him as to cutting the fruit. There are other points to be considered besides flavour; mere sweetness is not the most tangible proof of a first-rate Melon. I have seen Melons have the highest awards on exhibition tables which were totally unfit to hold a position in a well appointed dessert. Fruits tough like leather, with flesh of no depth, which required masticating like an Apple, are not among the qualities of a first-rate Melon. No connoisseur would tolerate such on his table.

It is the same with most other fruits. Those who have been accustomed to have the wants of their palate gratified with the finest qualities which can be produced in fruits, are not easily satisfied with what I have hinted at as being too much in evidence on exhibition tables. Young beginners should make themselves acquainted with the points which are essential to render the fruit of first-rate merit before they begin judging by flavour. If horticultural societies insert in their schedule rules (as numbers are doing), there is no help in the matter of making mistakes as to flavour, and judges will be relieved of a part of their duties, which are not always agreeable. During a lifetime (each season) engaged at such work one learns a thing or two.—M. TEMPLE, Carron, N.B.

HORTICULTURAL EXAMINATIONS.

UNLESS I am much mistaken, it will be readily conceded that examinations in horticulture have a sufficient bearing upon the future of gardening in this country to justify an occasional halt being made to consider whether their trend is beneficial or otherwise; and, whatever may be their influence, whether they are not capable of improvement. The present time appears opportune for a discussion of the several questions to which horticultural examinations, as at present conducted, give rise. The scheme inaugurated by the Royal Horticultural Society for the purpose of testing the knowledge of the rising generation of horticulturists has been in operation a sufficient length of time to enable us to form a fairly correct idea of the results that have been obtained, and to formulate an opinion upon them.

In opening the discussion on the questions that present themselves for consideration, I would first state that I have long had, and continue to have, a decided leaning towards examinations; and also that I fully appreciate the public spirit shown by the Council of the Royal Horticultural Society in formulating the scheme that now occupies a prominent position in the Society's programme. Therefore it is with no deep-seated objection to examinations, or in an unfriendly spirit, that I approach the question. On the contrary, it is with a strong desire to assist in devising some means by which the examinations could be so conducted as to bring about the results we all so earnestly desire.

The two questions of special importance in this discussion appear to me to be: Are horticultural examinations serving a useful purpose? If not, can they be so improved as to make them useful? A direct yes or no to either question would not meet the necessities of the case. They ought to be fully considered from the several points of view, and the answers so formulated as to indicate the course that should be taken to insure satisfactory results. There is no doubt whatever in my mind that those examinations might be made to render valuable service in testing the knowledge of those individuals who submit themselves to them. I am equally well satisfied that if they fail to do this it is because of some defect, trifling it may be, in the scheme under which they are held.

In turning our attention to the Royal Horticultural Society's system we may with advantage endeavour to ascertain the object the Council had in view in its formulation. Unless I am under a misapprehension the object was the provision of a means by which the education of young gardeners might be encouraged, the knowledge of those attending courses of lectures on technical horticulture be tested, and the ability of those who had adopted gardening as a means of livelihood demonstrated.

If these were the objects of the scheme we shall be fully justified in stating that it has succeeded in effecting the first of the three. There can be no doubt whatever that the examination has given a great stimulus to the education of young gardeners in matters having a direct bearing upon the work of the garden. They may not have taken advantage of the facilities for the acquisition of knowledge in exactly the right way; but to stimulate a desire for a fuller acquaintance with the gardening art than can be obtained from rule of thumb practice is a distinct gain, and this much I gladly place to the credit of the scheme.

If the second of the objects was as I have stated, it must be said that in this particular the scheme has unquestionably failed. It was to me a foregone conclusion that the examination must fail, and I based my estimate on the fact that an examination ranging over the whole domain of horticulture could not satisfactorily test the soundness of the teaching given at a course of lectures on one branch of it. It is surprising the examinations should have been projected for that purpose, and still more surprising that the local educational authorities should have considered that they could effect such an object. It was a matter of common knowledge that the lectures were being given in courses of three, four, five, or six, and that each course was devoted to some special branch of gardening, as fruit culture, plant culture, and kitchen gardening. What was being taught was certainly well known to the committees who had passed the syllabus of the several courses, and they ought to have known that a general examination could not properly show the extent of the information obtained by a candidate in attending five or six lectures on one section of gardening.

Let us for a moment assume that students attending a course of lectures on vegetable culture sat for the examination held in 1899, and then turn to the examination paper. We shall find that there are two questions only relating to the kitchen garden, one referring to Peas and Beans, and the other to salads. Those who had attended a course of lectures on fruit culture would be in a still worse plight, for the only question is one relating to the culture of fruit under glass. The thoroughness or otherwise of the teaching of any particular branch of horticulture can only be properly tested by an examination based on the syllabus. Had examinations been conducted on these lines within two or three weeks after the concluding lecture, it would have been readily seen whether the students had profited from the lectures they had attended. Had this been done, and students who had passed two or three of the special examinations sat at the general examination held at the close of the lecture season, their knowledge would have been put to a satisfactory test.—(First portion of a paper read by Mr. GEO. GORDON, V.M.H., at a meeting of the Horticultural Club on the 9th inst.)

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE, Jan. 9th.—Present: Dr. M. T. Masters (in the chair); Dr. H. Müller; Mr. Michael, Mr. E. im Thurn, C.M.G., and Rev. G. Henslow, Hon. Sec.

Horseradish Attacked by Rhizogryphus.—Some roots of this, as also of the Lily of the Valley, attacked by this mite, were received from Mr. Abbey of Avery Hill, Eltham, who forwarded a long list of plants likewise attacked. Mr. Michael observed that it is a subterranean species, and that although it prefers bulbs, it is very injurious to many, indeed, most other plants with fleshy roots, though it may not thrive equally well upon them. As a remedy Dr. Müller suggested lime and sugar or treacle, as being better and stronger than limewater, as well as more persistent in its action. Mr. Michael also observed that heat, as in boiling water, was destructive, but the mite resisted chemicals to a remarkable degree. With regard to the life history, it passes through several stages, commencing with the egg, this gives rise to a hexapod larva, then to the nymph, a very active octopod. After a new change of skin, in a large number of cases, but not in all, there emerges—without any discoverable cause—a being totally unlike the preceding, formerly known as Hypopus, having been thought to be a quite different genus. This has a soft body internally, but covered with a hard and usually chitinous integument. Its mouth organs are rudimentary, and it probably does not feed. It is provided with discs by means of which it adheres to insects such as ants, bees, beetles, &c., and to other small moving creatures. These it utilises as means of migration, clinging to them, but without being parasitic. As soon as a suitable environment is met with, the mite changes back into the last nymphal stage, and then proceeds to pass into the adult male or female condition. It may attack plants in all stages, except that of the migratory Hypopus. The Hypopus is practically impervious to chemicals, and can endure without injury exposure to heat and draught which would destroy the creature in any other stage.

Apples Injured by Hail.—Some fruit was received from Mr. Woodward of Barham Court, Maidstone, which had received severe injuries from hailstones. But, although the skin was cut through and the flesh exposed, this had dried up and so protected the interior, which had not at all decayed. The storm occurred on July 19th, 1899. Mr. Michael observed that when birds plunged their beaks into Apples through thirst, the injured spots usually resulted in decay.

FRENCH HORTICULTURAL SOCIETY.

THE members of this flourishing young Society, which has done so much under the generous policy of its Chairman, Mr. G. Schneider, to improve and strengthen the good relations existing between English and continental nurserymen and lovers of horticulture generally, held their eleventh annual dinner on Saturday last, at the Imperial Restaurant, Strand. M. Geoffray, the Minister for France in this country, occupied the chair, being well supported by numerous French and English friends of the Society, among whom we noticed M. Léon Clerc, Secretary of the French Chamber of Commerce in London, Mr. George Schneider, Mr. George Gordon, Mr. Harman Payne, Mr. Thos. Bevan, Chairman of the Floral Committee N.C.S., and others.

The Chairman proposed the health of Her Majesty the Queen, and this was followed by the toast of the President of the French Republic, by Mr. Harman Payne.

The next toast on the list was that of the Chairman, by Mr. Tucker, and in reply M. Geoffray expressed his pleasure at the useful work the Society was doing, and complimented the officials on the energy they had displayed in helping to promote good feeling between the horticulturists of the two countries, and he would couple Mr. Schneider's name with the toast. Mr. Geo. Schneider, in reply, thanked the Chairman for the honour he had done the Society by presiding at their gathering, and asked permission to give a few details of the progress made during the past year. He was pleased to say that the list of membership had largely increased. During 1899 they had elected eight perpetual honorary members, forty ordinary honorary members, fifty titular members, and thirteen corresponding members, or 111 in all. Instead of printing 500 copies of their annual bulletin it had been found necessary to print 600. From a financial point of view the progress was equally satisfactory. They had now a substantial sum invested in stock, which was productive of an annual income. The library had also been increased, and they were largely indebted to English nursery and other friends for help in various ways. Some of these were present, but he regretted that others who would have been there were kept away by illness, notably Messrs. G. Nicholson of Kew, Mr. Arnold Moss, and Mr. Drost. He would ask them all to drink to the health of their guests.

An opportunity was taken of presenting to Mr. Schneider a testimonial consisting of a pair of handsome porcelain vases from the young members of the Society in appreciation of his labours in their behalf.

Mr. Harman Payne responded for the guests, and proposed the toast of the absent members. Towards the close of the evening the company sang "La Marseillaise" and "God Save the Queen," following which a collection was made for the widows and orphans of the British troops now fighting in South Africa.

BIRMINGHAM BOTANICAL GARDENS.

THE visitor may always be sure of finding something in flower here, and this Christmastide there was a beautiful show of Begonia Gloire de Lorraine. The veteran Curator, Mr. W. B. Latham, quickly secured a stock of this plant when it was placed on the market. Considering the comparative dearth of flowers at this season of the year, this floriferous Begonia has made for itself a niche that no other plant could fill. The fine array of specimens in question was arranged in the aquatic house, a portion standing upon inverted flower pots and the other suspended from the roof, the former being supplemented by choice Ferns and other ornamental foliage plants. The whole was enhanced by two large specimens of the too little grown *Callicarpa purpurea*, the violet purple innumerable-berried racemes of which afforded a charming contrast to the rosy pink inflorescence of the Begonia.

A peep into the principal Orchid house revealed—considering the time of year—a fair display of bloom, composed chiefly of *Lycaste lanipes*, *Laelias anceps* and *autumnalis*, *Calanthe Veitchi* in quantity, and *Ceologyne barbata*, *Cochlioda rosea*, *Odontoglossum crispum*, *Saccolabium giganteum*, several forms of *Cypripediums*, such as the new and distinct hybrid *Deedmanianum*, a fine plant of *Stenei* with five or six spikes, *Lathamii*, *Chamberlainianum*, *nitens*, *cardinale*, *Sallieri*, *villosum*, and *Sedeni*. It may be remarked that the *Cypripedia* form a considerable feature in the large collection of Orchids here. There is a large number of unflowered seedlings, and of which Mr. Latham and his expert lieutenant, Mr. W. Deedman, are justified in expecting something good, according to their parentage, and the appearance of the remarkably fine foliage of several of the plants.—W. G.

THE YOUNG GARDENERS' DOMAIN.

MALMAISON CARNATIONS.

MALMAISON Carnations are amongst the most useful plants in cultivation, especially during the winter months. To propagate, the old plants should be layered in frames the first week in July. The compost to use for this operation may consist of equal parts of fine loam, leaf mould, and sand, well incorporated. Have the old plants which are to be layered well cleaned, and see that the ball of the plant is thoroughly moistened before taking it out of the pot, otherwise it will give great trouble. Place the ball well under the soil, so as to give plenty of room for layering on the top of it.

Layering is a simple operation, but layers are frequently spoilt either by cutting too deeply or not deeply enough. Each layer should have all the bottom leaves trimmed, and then be cut from one joint to the other, so that when it is made it will be a little more than half way through the stem; then with a peg, either made out of twigs or wire, fasten in the soil, always having the cut piece pointing downwards in the soil. As the layering proceeds give water to settle the soil around them, and keep the lights close. If the weather should be hot they will also require shading. Syringe them every afternoon on bright days when the sun has gone off the frame.

In from eight to ten days a little air may be admitted to encourage sturdy growth, and gradually give more as time goes on, until they will stand with the total removal of the lights. In from four to five weeks the layers will have rooted and be ready for potting. The size for this should be 3½-inch, which has been well cleansed and drained, using a compost of three parts of loam and one each of leaf mould, sand, and fine peat, with a little wood ashes. Pot the plants firmly so as to encourage sturdy growths; place in a cold frame, standing the pots on coal ashes, and keep them close for a few days until root action commences; also shade lightly from the sun on bright days. The watering now will have to be carefully done, never applying any unless necessary.

When the plants have a fair amount of roots around the sides of the pots they will require another shift, and 7-inch pots are very suitable. They will require a thorough washing, and also plenty of drainage. The compost should consist of ten parts of loam broken up in pieces the size of large Walnuts, two parts of peat, two parts of sand, two parts of wood ashes, one part of old mortar rubble, a little sheep's manure, charcoal, and a good sprinkling of Clay's fertiliser, well incorporated. Handle the plants very carefully, so as not to break any of the young roots, pot them firmly, and have the tops of the balls rounding, so that in watering none will settle round the stems of the plants. When potted stake each one, but do not tie them too tightly, and afford a temperature of 45° to 50° at night, 50° to 53° by day, and keep the house close for a short time. Do not apply any water for a few days after potting.

Malmaisons are lovers of plenty of air. Attend to the tying of the plants as necessary, also removing decayed foliage as it appears, for if permitted to remain any length of time it will cause other parts to become disfigured. The plants will require very little manure until the following spring, but weak liquid manure occasionally will do them no harm when the roots have found the sides of the pots. When the plants are showing their buds and are large enough to handle remove all side buds, leaving only the crown. As the days begin to lengthen and the sun gains power, the plants will require shading during the hottest parts of the day, and also the house will

need damping occasionally. It is good practice when very hot to syringe between the pots two or three times daily. Any time on perceiving green or black fly on the plants a little tobacco powder should be dusted on the affected parts, and also fumigate occasionally with XL All vaporiser, which will quickly destroy the pests.—P. R.

HARDY FRUIT GARDEN.

Raspberries.—*Preparing Ground.*—In establishing a new quarter of Raspberries the first essential is the preparation of the soil. The best material for the growth of Raspberries is a rich strong loam, but the best material requires to be thoroughly well broken up, so that it may have more capacity for holding food and moisture and admit of the roots ramifying readily. The strong-holding roots descend deeply, imparting strength and stability; the fibrous roots increase and multiply near the surface. Rich, deep soil is needed for both sets of roots, hence in the preparation of soil prior to planting trenching is the best method of procedure, not, however, bringing poor subsoil to the surface. This can easily be avoided by bastard trenching. Work in a liberal quantity of rich farmyard manure, especially in the lower spit of soil, as this is the only opportunity that particular portion can be manured, though nutriment from surface dressings will be washed down in course of time. Soil of a stiff character may be improved by the addition of old potting soil or gritty material, this being chiefly inter-mixed with the surface soil.

Planting.—Strong young canes which have been produced from the old stools are not so good for planting as vigorous, but medium-sized, canes, which have emanated from suckers at a distance away. The latter will be better furnished with the most desirable set of roots—namely, fibrous roots, and a tap root of a less woody character than is to be found in divisions of old stools. If these sucker growths can be lifted, the injured roots pruned, and be at once planted, they will soon take hold of the soil. Spread out the roots to their full extent in shallow, wide holes, raised in the centre, on which place the plant. Cover with some light, rich, prepared soil mixed with burnt refuse, spreading this lightly over them from the crown outwards, finishing with some of the finest of the staple soil. There are various methods of planting, some preferring lines or rows, others planting in clumps of three with a stake not more than 5 feet high in the centre. Place the plants a foot apart in a triangle. If in rows, plant a foot apart in rows 5 feet asunder. Wire for training the growths upon must be stretched between stout uprights of wood or iron.

All newly planted Raspberries will require pruning closely before growth starts. The weakest canes must be pruned close to the ground; stronger, having abundance of roots, within a foot of the soil. No fruit should be permitted the first season, as it is most desirable that the growth made be encouraged to develop in a vigorous manner for the production of fruit the following season.

Pruning Established Raspberries.—The winter pruning consists in reducing the number of canes to each stool, not allowing more than six to each, and these should be the strongest. Weakly canes, also the dead canes which have borne fruit, must be cut out entirely. Shorten the canes retained to the height of the stakes or trellis. When trained to stakes tie the canes round the central support. On wire spread them out at equal distances.

Manuring.—Newly planted Raspberries may be mulched lightly with littery manure. Established plantations should receive a liberal dressing of rich decomposed manure spread between the rows and round the stools, not digging or forking it in, but leaving it to decay.

Root-Pruning.—Though autumn is the best period for carrying out this work it may be done any time before growth commences, operating on trees that make too much wood growth and produce little or no fruit. A trench should be cut round at a distance of 3 feet from the stem, but it will be safer to do so only half-way in one season, dealing with the other half the following year. In cutting the trench all strong roots found are severed, ultimately cutting the jagged and broken ends smoothly. Preserve all fibrous roots for laying in again. The chief cause of strong unfruitful growth is the descent of the tap root and possibly other large roots into the subsoil. These must be checked by severing them smoothly. All the roots on one side having been dealt with proceed to fill in the trench again, mixing in with the soil wood ashes, decomposed manure, and a little turfy loam, making the whole firm, and spreading the fibres preserved horizontally. Mulch with some light manure.

Wall Trees.—*Pruning.*—Apples, Pears, Plums, and Cherries on walls not yet pruned should be attended to. Horizontally trained, fan trained, and cordon trees ought not to have the main branches closer together than a foot. Old trees having large branches and clumps of spurs must have more room, as it is desirable to afford light and air

freely to every part in summer. Therefore thin out the spurs, partially shortening the most elongated. Foreright or side shoots, whether summer pruned or not, may be shortened to a few buds with a view to these forming fruit buds. These are more likely to develop quickly if the shoots which extended long were shortened to six leaves in summer in the case of trees which bear fruit on spurs. By doing this the basal buds on each shoot are largely encouraged to form fruit buds.

Cleansing.—Trees are all the better for a dressing of some kind, especially if they have been affected with red spider on the leaves last season. These insects pass the winter on and in the crevices of the bark. The caustic soda and potash solution sprayed on the trees destroys insects and eggs, leaving the wood clean and bright. An insecticide for applying with a brush is composed of half a pound of softsoap in a gallon of water, 1 pint of tobacco juice, and a handful of flowers of sulphur, all thoroughly intermixed.

FRUIT FORCING.

Cherry House.—Give due attention to watering trees in pots and syringing on fine days, damping occasionally only when the weather is dull. Maintain the night temperature at 40°, 45° to 50° in the daytime by artificial means, ventilating at 50°, and allowing a rise of 10° to 15° from sun heat, with full ventilation, closing at 50°. Scrutinise the trees closely for aphides, and if there be any trace of the pest take measures at once to eradicate them.

Cucumbers.—Maintain the night temperature at 65°, allowing 5° more in mild weather, whilst it may be 5° less on cold nights, 70° to 75° by day, and 80° to 85° from sun heat. When the external air is mild a little ventilation may be given at 80°, closing before the temperature is reduced below that degree, so as to raise to 90° or 95°; but if the external air is cold, though the sun shines, it is better to allow the temperature to advance a little beyond the above limits than to admit cold air, which injures the foliage, also causing the fruit to become stunted and curl at the end. Plants in bearing will require to be examined about twice a week, removing all weakly, superfluous, and exhausted growths, reserving as much of the young bearing wood as is necessary to fill the allotted space, stopping the shoots above or two joints beyond the show for fruit.

Young plants coming into bearing should not be allowed to bear fruit too soon, and by no means be overcropped. They are greatly assisted by removing staminate blossoms, also superfluous pistillate flowers as they appear. Tendrils also should be pinched off. The supply of moisture, both at the roots and in the atmosphere, must be regulated by circumstances and external conditions. Syringing should not be practised on the foliage, except a light sprinkling in the early part of bright afternoons, damping the floor at about 8 A.M. and 2 P.M. Encourage the roots to spread on the surface of the bed by adding lumpy loam from time to time, with which may be incorporated a little well-decomposed cow manure or fresh sweetened horse droppings. When roots are had in this manner the plants may be fed to any extent by sprinkling a mixture of two parts bone superphosphate and one part powdered saltpetre, mixed, on the surface, at the rate of 2 or 3 ozs. per square yard every fortnight or three weeks, with a light dusting of soot between times.

Keep a keen eye on the plants for aphides, and fumigate several times moderately and consecutively rather than once severely. The evening is the best time for fumigating, following it up by another dose the following morning. If mildew appear, paint the hot-water pipes with a cream formed of flowers of sulphur and skim milk. The fumes given off will kill white fly and mildew, also red spider. Canker is unusually prevalent; freshly slaked lime rubbed into the affected parts will arrest its progress.

Peaches and Nectarines.—*Early Forced Trees.*—Fertilise the blossoms as the pollen becomes ripe, using a camel's hair brush, feather, or rabbit's tail mounted on a small stick; these are better and more effectual than shaking the trellis. When the fruit is well set syringe the trees occasionally in the morning or early part of the afternoon, to assist the fruit in casting the remains of the flowers. In bright weather syringing may be practised in the morning and afternoon; but when dull have recourse to it in the morning, this and damping in the afternoon being sufficient. The water employed must be of the same temperature as the house, and the inside border should be duly supplied with it. Disbudding will soon require to be attended to, but it must be done with discretion at this early season, it being better to remove a few shoots daily from a tree than many at a time at distant intervals. The night temperature may now be maintained at 55° to 60° on mild nights, 60° to 65° by day, 5° less as the medium when the weather is severe and dull, admitting a little air at 65°, not allowing an advance over 70° without full ventilation, always excepting a little left at the top of the house constantly.

Second Early Forced Trees.—When the blossoms show colour on the trees started at the new year syringing must cease, but the paths and borders should be damped in the morning and afternoon. Supply water as required to keep the border in a thoroughly moist state. Keep a sharp look out for aphides. If there be any fumigate the house on two or three consecutive evenings moderately, which will be sufficient to keep the pests under until the fruit is set. In case of an excess of blossom buds, and they are abundant this season, also promising,

draw the hand the contrary way of the growths along the under side or back of the trellis, so as to remove the number of bloom buds, which will increase the vigour of those left, therewith tending to a more even and better swelling of the fruit after setting.

Succession Houses.—Push forward the pruning of the trees, cleansing of the house, dressing the trees with an insecticide, and re-adjusting them to the trellis, leaving plenty of room in the ligatures for the swelling of the branches. The surface of the border may be pointed over with a fork, but not disturbing the roots, the loose soil removed, and fresh loam supplied, sprinkling on it about 4 ozs. per square yard of a mixture of steamed bonemeal three parts, sulphate of potash two parts, and sulphate of magnesia one part, mixed. If the borders are at all dry they should be given a thorough watering. Houses, however, that have movable roof-lights, and these being off, will not require any water, the soil being thoroughly moist from rain.

THE BEE-KEEPER.

CONFINING BEES IN WINTER.

A COMMON error often made by bee-keepers in their anxiety to prevent the bees suffering from the extreme cold is to confine them to the hives by closing the entrance. This ought only to be done when the colony has to be removed some distance by road or rail. Ample ventilation should then be provided by using a piece of perforated zinc to prevent the bees leaving. Our attention has lately been drawn to a case in point. The entrance to a frame hive had been accidentally closed, how long we were unable to discover; but from the condition of the bees they had probably been confined for at least a month, and there was not a living bee in the hive.

What is the cause of bees dying in this manner when the entrance is closed for a few weeks at midwinter? We cannot say they were suffocated, as it was impossible to close the entrance quite closely, although there was not sufficient space for a bee to pass through. The small space unclosed was the fatal error. The first fine day after the bees were made prisoners, when the sun was shining directly on the entrance, they would do their utmost to leave their hive. Being foiled in the attempt, they gradually became numbed owing to the low temperature that prevailed, and so were unable to return to the cluster. This alone shows what a dangerous practice it is to close the entrance at any time.

MAKING CANDY.

We are reminded there are constantly new readers, and as we have recently advised some of them to feed their bees that are short of stores at this season with candy, it may be of some assistance to them if we state, as briefly as possible, how to make it. Candy is not always made properly at the first attempt, but, like many other things, practice makes perfect, and with a little patience a novice may soon prove how easily a fine-grained, moist, soft candy is made. If it is coarse-grained the bees will not be able to consume it, and during the prevalence of fine weather they may be seen carrying it from their hive. We have had experience of this, as we were not successful in our initial efforts.

We prefer a paraffin or gas stove, as they are clean, and the heat can be regulated, which cannot be done so readily over an open fire. Use a fine granulated sugar, a brass or enamelled iron preserving pan should be used, into which put 12 lbs. of sugar, two imperial pints of water, and two teaspoonfuls of cream of tartar. Set on the stove, stirring constantly to prevent burning, until it comes to the boil. Turn the burners slightly down to prevent boiling over until the mass begins to settle down to boil, which is readily known by its frothiness. Continue stirring, and have ready a cup of cold water for testing it, and with a teaspoon lift out a little syrup and drop it into the water. If it lie at the bottom of the cup so as to lift like very thick paste or putty it is just right, and ready to be removed from the fire. If too much boiled the syrup will be hard and crisp in the water. This may be remedied by adding a little water to the syrup after its removal from the fire.

Much will depend on the class of sugar used as to the length of time required in boiling. If the most suitable for the purpose is obtained two minutes will suffice, whereas another class of sugar similar in appearance will take ten minutes. The pan should then be placed in cold water to hasten the cooling process. Whilst this taking place prepare some shallow dishes, and into these place sheets of thin paper, slightly larger than the dish. When all is in readiness return to the pan of cooling liquor, which should now be kept constantly stirred. At first it will be dark in colour, but as it cools it will have a greasy appearance, gradually getting whiter and stiffer. It should then be poured into the shallow dishes and allowed to cool. The candy may be removed from the dishes as soon as cold, and will then be ready for use.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Begonia weltoniensis (*Amateur*).—This is a useful plant for conservatory decoration, as well as two or three other kinds of a similar nature. The earliest plants may be shortened back and placed in a temperature of 50° until they show signs of growth, when the old soil should be shaken from their roots and the plants repotted in a fresh compost. The plants can be placed in the same size pots or smaller. If the latter they will soon need repotting. They will be found to succeed well in three parts of loam to one of leaf mould, with a liberal quantity of sand according to the texture of the loam, and one-seventh of old Mushroom-bed refuse. Water with care until the plants are growing freely. They will start well in a vinery if no better position can be found for them.

Erica candidissima (*P. H.*).—Market plants of this variety that flower well cannot readily be had in the same condition the following season. If cut back, allowed to start into growth, then repotted and given an extra season, removing any flowers that appear, they make splendid plants. The same may be said of *E. hyemalis* that are cut back late. They often only make short growth, which flowers profusely if allowed to do so, and, strange to say, these plants have much better coloured flowers than those grown for market. If the flowers are removed and the plants allowed to extend their shoots good stock will be produced with shoots 18 inches to 2 feet in length. Keep these plants perfectly cool, give abundance of air and water carefully, but never allow them to become dry.

Where and How to Keep Loam (*E. T. H.*).—We presume the loam is the ordinary yellow or hazel cut in turves of about 3 inches thickness. The best place for it is an open situation, though usually placed by a hedge, fence, or wall on a dry bottom, that is, water on the surface draining away from it. The turves are best stacked grass side downwards in piles longer than wide; we prefer the stack twice as long as wide, and the height about equal to the width, taken up perpendicular at the sides and ends, and at the top span-roofed like the roof of a house. Thus ridged the stack cannot be deluged by heavy rains, and has a chance from its sides and ends being exposed to the atmosphere to become thoroughly aerated and nitrified, turf stacks gaining in nitrates considerably by such exposure. It will absorb some moisture from the soil and remain in good condition indefinitely, the roots of trees not having access to it.

Solanum capsicastrum (*Tyro*).—As your conveniences are extremely limited, we should not cut back the plants until April, then by the time fresh growths push the weather may be warm enough for their being placed in a very sheltered position outdoors, protecting them from frosts which may occur in May, and cutting winds. More than half the old soil should be removed from the roots after fresh growth starts, repotting firmly in good turfy loam, a sixth part of crumbled manure, and a tenth of wood ashes. The pots may be plunged just over their rims in a sunny border for the summer, standing them on smaller pots in the ground to prevent worms passing to the roots. They must be watered as needed, which will not be half so frequently as if the pots were exposed. Clear soot water is good for Solanums when the pots are filled with roots. Some persons plant them out towards the end of May, lifting carefully, and potting firmly in September, watering well, sprinkling the foliage, and letting the plants stand in the shade for a time for keeping the leaves fresh and inciting quick root action. We have seen fine plants grown in that way, but all persons do not succeed alike.

Forcing Seakale (*Nemo*).—You will find tubs, similar to that shown in fig. 12, extremely useful for the forcing of Seakale. The practical

FIG. 12.—TUB FOR SEAKALE.

article by Mr. E. Barrow, on page 52, will probably convey all the information you require. If such is not the case, do not hesitate to write again, as we are always glad to be of assistance to our readers.

Pruning Orchard House Fruit Trees (*V. C. S.*).—The removal of crowded branches, those that cross and interlace with others, small spray growing in the interior of trees, and dead portions of wood are the chief details necessary in keeping trees healthy and fruitful. Though thin disposal of the branches is very essential, severe thinning at one operation is not desirable, should the trees be exceptionally full of rank growth in consequence of previous years' neglect. A reasonable amount may, however, be taken out, each branch removed being cut close at its junction with another, which will prevent young shoots breaking strongly afterwards. Among a host of crowded branches there is invariably an amount of dead shoots. These of course may be cut out. The access of air and light prevents wood dying if trees are otherwise healthy, and a free extension of the branches within moderate limits, so that the foliage can properly perform its functions, favours the production of sturdy fruit buds instead of a preponderance of wood growth. A little regulation yearly, especially in the autumn before the leaves fall, thinning out any obstructing branches then, serves generally to maintain large standard garden and orchard fruit trees in shapely form and prolific bearing.

Potatoes in Pots (*A. N.*).—Extra early, if not very heavy crops of Potatoes can be had from 9-inch or somewhat larger pots, set on shelves at the back and on the beds and front stages of vineries and Peach houses being forced. The earliest short-topped varieties are to be preferred for this method of culture. Fairly strong sets, each furnished with the first strong sprouts only, are desirable, these having been previously started in moist heat. Old Chrysanthemum soil, or failing this a mixture of two parts of light loam to one part of old Mushroom-bed manure with a very little soot added, answers well. Drain the pots roughly, and plant a single set in each rather deeply, good room being allowed for a top-dressing to be given when the shoots have extended above the level of the rim of each pot. Water carefully at first, only enough being given to keep the soil just moist, and when the pots are becoming well filled with roots do not let the soil become dry. Fairly deep boxes and large pots may also be utilised for a similar purpose, the sets being disposed 6 inches apart each way.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (F. K.).—1, *Begonia manicata*; 2, *Phormium tenax*; 3, *Maranta Veitchi*; 4, *Begonia Ingrami*; 5, *Peperomia argyrea variegata*. (P. B.).—1, *Selaginella caesia*; 2, *S. Kraussiana*; 3, *S. apus*. The Orchid is *Oncidium tigrinum*. (C. M.).—1, *Asplenium flaccidum*; 2, *Pteris cretica albo-lineata*; 3, *Cyrtomium falcatum*.

SIR JAMES BLYTHE ON THE AGRICULTURAL SITUATION.

SIR JAMES has evidently got an idea that the long lane is near a turn—that there is a chance, indeed a certainty, of a revival in agriculture. He considers we have slept too long, that it is high time now to wake out of sleep; he sees the giant stretching and yawning, and he prophesies great things. We confess we do not altogether follow the line of his argument; we have only a life experience of hard farming to set against his experience of model farming, with a large income to back it. He knows, or ought to do, as President of the British Dairy Farmers' Association, far more of dairy work than we do; but dairy farming is not everything; nor do we see in it a way for the salvation of the general farmer.

"In the multitude of councillors is wisdom;" that, of course, goes without saying. But what if we are heretical enough to doubt the ability of our advisers? Sir James lays great stress on the multiplication of societies more or less connected with or bearing upon agriculture. Of what practical value are many of these societies? The training centres are all very well in their way, but do they attract and train the right material? The experimental stations are good in their way, but do they not often only arrive at negative results?

As for the shows, we will begin with the Royal—a fine institution in itself, but cumbersome in its machinery, and getting rather behind the times. There seems no adequate return for its vast expenditure. The same may be said of other societies. We do not think that England will benefit to the extent Ireland has done, through any organisation society; there is such a gulf between the two classes of farm management. The National Poultry Organisation possibly has a useful future. The chair for agriculture will mostly benefit the holder. We understood that the training colony at Lingfield was mainly intended to pull up those male members of society who had drifted away from their proper sphere. An agricultural side to middle class schools may be of benefit, provided the teachers are the right men.

Sir James talks largely of the greater productions of the minor farm commodities. We quite agree with him there; more might be done. Woman lost us Paradise. Sir James argues that woman is to regain the earthly equivalent. He lays the greatest stress on the desirability of women cultivators. He recurs to it again and again. He speaks of it as easy, pleasant work—merely a pastime. We know the female sex does predominate, but can he really be in earnest when he talks of women filling up the gaps left by the exodus of the village labourer to the towns? It is wonderful what hard work women can do, but it seems hardly fair to expect them to do the work usually delegated to men. What class are the women workers to be taken from? Not the peasant class, they are fully occupied. The lower middle class find occupation as shop girls, teachers, telegraph clerks, and so on.

If the middle class, or as Sir James has it, "women of gentle birth," are to be the saviours of agriculture and the pioneers of small industries we are sorry for them. It is no joke producing poultry, fruit, butter, eggs, and flowers; it means much hard work, harder than Sir James imagines. He must first of all breed a class of women for his purpose, as they don't exist now. They must be intermediate between Amazons and those hard unsexed women who used to be found on Northumberland and Scotch farms and women from the pit brow. We thought we had seen the last of this state of things, and that in these latter days women could find employment in work more fitted for their physical strength.

We do thoroughly approve of any scheme that will bring rural children more in touch with their surroundings, and doing away with

some part of the educational code, and a substitution of agricultural classes. The change will be attended with many and serious difficulties, and there will be a great many mistakes made at first. We shall want to teach too much and go too far.

He is a bold man who will venture to discuss the subject of land tenure. Sir James thinks and advocates that occupying owners of small holdings will do better for themselves and better for the public than tenants of larger farms. He prophesies that this new century will early see large occupations of 200 to 400 acres cut up into small plots of 10 or 50 acres, thus finding employment for a man and his family. Men of this class have the hardest lives of any in the United Kingdom—their work is never done, and unless prices rise materially their profits are infinitesimal.

On the other hand we are to have large co-operative farms of 5000 or even 10,000 acres, where everything is to be done in a purely commercial manner. All new labour-saving appliances, best of machinery, and everything first-class. This, says Sir James, would solve the problem of scarce labour; only a small force would be needed, they would be of the best class, and highly paid. We think that here Sir James strikes a true note. Why should agriculture be the only industry which cannot be worked on a large scale? We see everywhere around us huge business firms, and the larger and more extensive they are the greater their success. Apply the same process to farming, but of course in the same practical manner. If buying and selling for 10,000 acres could easily be done by one person of reasonable competence and energy, eight or ten practical bailiffs would relieve him of all responsibility as to the carrying out of general orders, and he would be able to devote his time, apart from the market days in each week, to casual inspection of the various sub-departments, and the formulation of new enterprises.

On a farm of such extent the shepherd would be a man of the highest experience and character, and would be responsible for the well-being of the entire flock, as well as for the management of the staff of assistants who would carry out the work under his direction. The same system would apply to the cattle, horses, &c., and the whole could be attended in emergency by a properly qualified veterinary surgeon, who would be specially retained.

The blacksmith's and wheelwright's work would all be done on the premises, and middleman's profit saved, but great strictness would have to be exercised to prevent leakage in the way of commissions, but if the superintendent had a sufficient salary, and were worthy of it, there should not be much difficulty in preventing it.

We have great doubt as to the likelihood of a large increase in the number of peasant proprietors, or rather we might say proprietors of 50 acres, such as the old yeomen, unless a great advantage be given to small farmers (by the Government) in the purchase of their farms by very favourable terms in connection with the sinking fund.

After the present war is over we may not hear much of the sinking fund for a while.

WORK ON THE HOME FARM.

We have had more heavy rain, and flood water is visible in many parts. The land generally is too wet to take horses upon, and there is little carting to be done. For a few days, until the land dries again, we had better have a general cleaning up. The stackyard may receive extra attention, and refuse from every nook and corner taken to the compost heap.

The fowl houses will do with a good cleansing and whitewashing, the manure being put in a heap in the tillage shed, ready for turning and eventual mixing with superphosphate for the Mangold crop. The super might with advantage be bought now and stored; the price is likely to rise, and it could never be more conveniently fetched from the station or manure works.

Labour difficulties are becoming still greater. We hear of eight farm servants having enlisted from one parish, and our informant fears he is likely to lose the ninth. Fully one-third of the ploughmen will have left, and there are no spare labourers to take their places. To bring men back from the towns much higher wages are required; but farming can find no more cash—prices of produce will not allow of it. We hear farmers declare that this will be the worst year of their experience.

Turnips are about finished, and farmers are loth to begin consuming their Swedes; they are shy of realising how bad they are. Many sheep are being marketed and killed that should have been on

Swedes until May, and this accounts for the slackness in the mutton trade. Beef, too, after being dearer at Christmas, is a little cheaper again, and this may also be due to the same cause that has affected mutton.

Potato markets are very firm, another rise having taken place since Christmas. They are relatively dearer in the country than in the markets, which is a very good omen for the future. Sorting and delivery is general amongst growers, and stocks are very small for the time of year. There are many bad ones, the yield is disappointing, and only a good price can produce a fair return per acre.

KINDNESS TO ANIMALS.

As I imagine "our Journal" desires to encourage this, as well as every other good horticultural and agricultural tendency, I propose to mention two instances, much to be admired, which have lately come under my own observation. In the large county town in which I reside, in one of its principal streets, a fine Hampshire hog, or Berkshire pig, might have been observed just before Christmas progressing with much difficulty—presumably he had been overdriven. Presently he rolled over on his side, and lay there, declining to get up. Perhaps he held with John Bunyan, "He that is down need fear no fall." His owner went off to obtain a cart; and poor piggy was left to the tender mercies of the street boys, who at once swarmed round him like flies, the least of their cruelties being jumping up and down on him.

Just then two rather young ladies passed by on their way to their drawing lesson—or rather did not pass by. With flashing eyes and imperial gestures, they ordered the boys off, who, strange to say, slunk away. The next thing was a careful diagnosis of the patient, with a prompt decision that it was water that was wanted. This they darted off at once to get. The first shop refused; the next granted an abundant supply. Mr. Pig at once plunged in his snout, drank off a whole bucketful, then rose up of his own accord, and sauntered off to his destination, amid the cheers of the bystanders, no doubt grunting out his gratitude to his charming benefactresses.

The same two young ladies shortly after met a dog in the park. It was a very dirty dog, and a much neglected one, a big rough mongrel, half starved, who had strayed off to die there. At once the eldest girl posted off home, leaving her sister to watch over it. She brought back her mother's best macintosh, which had been readily lent for the purpose. Then the two girls struggled back, carrying in their arms the poor beast. It was tenderly received, sat up with all night, fed with bread and milk and other restoratives, but it died in a fit the next morning, and had to be buried in the garden, where it is to be hoped it will show its gratitude next summer by promoting an extra supply of fine Rose blossoms. Such good Samaritan maidens deserve much admiration.—A. C.

PROPER FORM OF A DAIRY COW.—She should possess a long, thin head, large nostrils for plenty of air, great breadth between the eyes, high forehead, a bright clear eye, sound teeth, thin neck, deep through the chest with large lung capacity, long and large backbone for plenty of nervous force, broad hips, high pelvic arch, thin thighs, well apart, giving plenty of room for a good udder. She should be deep through the flanks, with plenty of store room for food. The udder should be well developed, running well up behind and well forward on the body, with large milk veins, teats set evenly on the four quarters and of good size. A cow with these points well developed indicates that she is descended from a line of dairy cows and will rarely prove a failure if properly handled.—A. G. JUDD (in "American Agriculturist.")

WHERE THE STRAIN IS FELT.—Where is the greatest strain to a horse whilst moving a heavy weight? Is it not his hocks and hind legs? Do we not have this question answered at every sale we attend? If one animal has a better hock and hind leg than its neighbour with other points equally good, do not we see it invariably makes the most money? Yes; the hock is the great propelling agent of the horse, and I think the readers of this note will agree that if we have not quite the same coarse appearance in the draft horse of to-day, we have a more evenly balanced animal, with just as much size and far better feet and legs than in the olden times; consequently, a horse possessing far better wearing material, which is, after all, what our brewers and other large buyers want. They do not mind paying the money, but they want a horse that can stand the work for years, thus getting remunerated for their outlay.—("Farmer and Stock-breeder.")

HANDLING BUTTER.—It is marvellous how hard old customs die, and that is much to be regretted as far as handling butter and milk is concerned. As regards butter the hand need never come in contact with it, as we have often before said. There are the "Scotch hands" to take it from the churn, the "dairymaid" to press out buttermilk, rolling boards to bring it into shape, and beaters to make up the pounds, half-pounds, or pats. And then either the "Scotch hands" or beaters may lift the butter to the scales or elsewhere, so that it is easily enough seen that no human hands need come into immediate contact with the commodity. But, to-day, not one dairy in twenty throughout the country makes use of the appliances, but handles the butter to a most undesirable extent, and in the West of England actually beats the cream about with the naked hand until butter comes, using no churn at all.—("Rural World.")

BARR'S SEED GUIDE NOW READY (FREE).

BARR'S SEEDS

OF FINEST SELECTED STRAINS AND TESTED GROWTH

THE BEST SEEDS IN THE WORLD for securing a supply of Vegetables "the year round," and for keeping the Flower Garden always gay, and with abundance of Flowers to cut for vases and bouquets; also Seeds of Plants for Greenhouse decoration summer and winter.

BARR'S SEED GUIDE contains a select List of the best Vegetables and the most beautiful Flowers for Garden and Greenhouse. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors, SENT FREE ON APPLICATION.

BARR'S 21/- COLLECTION OF VEGETABLE SEEDS contains a liberal assortment of the following useful Vegetables: Beans (Broad and French Beans), Beet, Borecole, Broccoli, Brussels Sprouts, Cabbage, Capsicum, Carrot, Cauliflower, Celery, Colewort, Corn Salad, Cucumber, Cress, Endive, Herbs, Leek, Lettuce, Melon, Mustard, Onions, Parsley, Parsnips, Peas, Radish, Salsify, Savoy Cabbage, Scorzoneria, Spinach, Tomato, Turnip, and Vegetable Marrow.

OTHER COLLECTIONS of BARR'S VEGETABLE SEEDS, 5/6, 7/6, 12/6, 42/-, 63/-, and 105/-.

These Collections sent carriage paid on receipt of remittance. Full particulars on application.

BARR'S CHOICE FLOWER SEEDS.—The "Seed Guide" contains a Select List of all the most beautiful Annuals and Perennials. Special Collections for all purposes, and many Sterling Novelties.

All Seeds sent Carriage Paid on receipt of remittance.

BARR & SONS,
12 & 13, King Street, Covent Garden, London.
Nurseries: LONG DITTON, SURREY

ONION—NE PLUS ULTRA.

AWARD OF MERIT, R.H.S.

The Finest and Largest Onion for Exhibition Purposes.
2/6 PER PACKET.

Special Prizes for the best 12 Onions will be given at the Hemel Hempstead Horticultural Society's Show.

LEWIS DUNBAR, SEEDSMAN, HEDEL HEMPSTEAD

ALL WHO WISH GRAND RESULTS should use THOMSON'S IMPROVED VINE, PLANT and VEGETABLE MANURE. This valuable Manure is yearly growing in public favour. Can be had of all Nursery and Seedsmen, or direct from the makers, WM. THOMSON and SONS, Ltd., Tweed Vineyard, Clovenfords, Galashiels, N.B. Price Lists and Testimonials on Application. 1 cwt. and upwards Carriage Paid to all stations in Britain and Ireland. London Agent—Mr. J. GEORGE, 14, Redgrave Road, Putney. Agent for Channel Islands—Mr. J. H. PARSONS, Market Place, Guernsey. Also THOMSON'S SPECIAL CHRYSANTHEMUM MANURE. ½ cwt. Carriage Paid to all Stations in Britain and Ireland.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—**HIRST, BROOKE & HIRST, Ltd., Leeds.**

HEATING APPARATUS for Greenhouses and other Buildings. Catalogue free of all kinds of Hot Water Pipes, Wrought and Cast Iron Boilers, Radiators, Cisterns, Pumps, Baths, &c.—**JONES & ATTWOOD, Stourbridge.**

COTTAGE GARDENING; being an Essay to which the Royal Horticultural Society awarded Mr. W. EGERTON HUBBARD'S Prize, February 16th, 1870. By E. W. BADGER. Third Edition. Price 3d.; post free, 3½d. Office: 12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

GREENHOUSES from £3 5/-; **VINERIES**, **CONSERVATORIES**, **FRAMES**, **SUMMER HOUSES**, &c. Illustrated List Free. Makers to H.M. THE QUEEN and H.R.H. THE PRINCE OF WALES.

E. B. HAWTHORN & CO., Ltd., London Works, READING. (Name Paper.)

ECKFORD'S SPECIALITIES

ONLY GENUINE DIRECT FROM WEM.
AWARDED 46 GOLD & SILVER MEDALS

SWEET PEAS!

The BIGGEST SUCCESS of all is **ECKFORD'S GIANT SWEET PEAS**. The PURITY and STAMINA of these Home Grown Stocks are so conserved by SPECIAL METHODS of CULTURE that the seeds are PHENOMENAL for UNRIVALLED STRENGTH and VITALITY, and with proper cultivation, give the HIGHEST POSSIBLE MAXIMA of results! Prizes offered in 1900 alone exceed £40! Collections from 1/6 upwards.

(See particulars in Catalogue.)

See beautiful plate of SWEET PEA NOVELTIES for 1900, sent gratis with each Catalogue.

CULINARY PEAS!

ECKFORD'S CULINARY PEAS are positively UNRIVALLED by any on the Market for FLAVOUR and CROPPING CAPACITY! ENORMOUS YIELDS under favourable conditions. Collections for 5 months continuous supply (See page 2 Catalogue.)

PURE VEGETABLE SEEDS!

Results from ALL QUARTERS prove that **ECKFORD'S SEED**, for PURITY, VIGOUR, and YIELD, are the CHEAPEST and BEST ever offered to the Public! Collection for 12 months supply, 12/6, 21/-, 42/-, 63/-, 105/-, all carriage paid. Other Collections, 2/9, 5/-, 7/6, post free.

CINERARIA (SILVER MEDAL STRAIN). Giant Flowers, splendid habit, unequalled!
PRIMULA SINENSIS. Unique Novelties and Grand Collection of named varieties
PANSY. World-famed strain of FANCY, SHOW, PEACOCK, and FLAKED VARIETIES!
VERBENA. RENOWNED RACE of EXCEPTIONAL MERIT!

Don't buy till you have seen it!

WHERE GARDENERS MEET.

A CHAT ABOUT SOCIETIES.

IN the first place let it be understood that the word gardener is used here in its broadest sense, and does not apply solely to the professional element. Every man is included under the title who cultivates a garden and takes a pride in it, whether for pleasure or profit. There is something in gardening which tends to develop the communicative side of a man, and, perhaps, it was this characteristic which led to the formation of horticultural societies. This spirit of fellowship is fully understood among gardeners, and it forms a link which binds the sympathies of those imbued with a mutual love for the gentle art.

Illustrations of this are continually arising. Study the human side of a big flower show, and observe the interested conferences taking place among the little groups of gardeners, or listen to the animated arguments of those who critically examine the exhibits and the awards. The same spirit is apparent when one gardener drops casually in to see another and to "have a look round." Follow the pair through the garden, note the eager conversation as they discuss the successes and failures of matters horticultural and social, and you will realise at once the meaning of the gardeners' communicative spirit. The amateur and the cottage gardener alike possess it. The former would not take nearly the same interest in his plants and flowers if he alone saw them, and he feels that he has got some reward for his labours when his neighbour looks over the fence and admires the result of his efforts. The gardener is no recluse; he loves the companionship of those who share his sympathies, and wherever gardeners meet there gardening will be the topic of conversation.

At the mention of horticultural societies the doings of the leading bodies at once suggest themselves to us, and in them we have remarkable illustrations of progress and advancement. Every reader of the *Journal of Horticulture* has doubtless read in its pages of the fluctuating fortunes of the Royal Horticultural Society during the last

fifty years; at one time at the height of prosperity, then in the depths of adversity, followed by another slow rise to the position it now occupies—a position creditable to everyone connected with it, and one holding out possibilities of further advancement in the cause of gardening. Other leading lights among societies in the provinces have risen from small beginnings, and now hold positions of wealth and influence. We admire the energies of the gardeners at Shrewsbury, Edinburgh, York, and many other places where high-class shows are now held under the auspices of important societies.

Popular flowers, too, have their own bands of brotherhood, so to speak, such as the Rose, Dahlia, Carnation, and Chrysanthemum. The latter is one of the wonders of the horticultural world. We know how the National Society has developed from the infant gathering of a few Chrysanthemum lovers, and like Mushrooms, similar bodies affiliated or independent have sprung into existence, not only in large towns but in country villages, and one and all are illustrative of the fascinating powers of the autumn queen.

In scores of country villages there are healthy gardening societies, supported partially or wholly by amateurs, and it is to the good work done by many of these that I would particularly draw the reader's attention. The most prosperous societies are invariably those having the financial support of local gentry, and the horticultural assistance of their gardeners; but these are not indispensable, and it reflects great credit on the working men members of those bodies which are practically self-supporting. There are numerous places in the country having a kind of horticultural society which holds an annual summer show, but after it is over the whole thing is forgotten till the time again rolls round. In such cases, what should be the chief aim of a gardening society—viz., mutual improvement—is missed, and the best work is done where periodical meeting nights are in vogue, particularly through the winter, for the discussion of matters appertaining to gardening.

There are some people who say that it is only a mercenary spirit which prompts exhibitors to compete. Let it be said to the credit of many societies that their members are not imbued with such feelings, but grow and exhibit their produce mainly for credit and honour. I know more than one society that guarantees no prize money at all, and yet it always has good shows. It is fully understood amongst the members that points will be given to those occupying first, second, and third places in each class, but whether these points represent any money value depends entirely on the receipts. On one or two occasions, through bad weather and other causes, the receipts have been swallowed up by the expenses, and the exhibitors had to be contented with their points. They might have been disappointed, but the entries for the next show were just as numerous. This proves that it is not with the sole idea of gain that gardeners become members of societies and exhibit their productions; there is a deep love for the occupation at the root of it all.

Among other benefits resulting from the existence of a flourishing village horticultural society is the all-round improvement in the gardening. I could point to villages, possessing no society with its stimulating effects, where cottage and amateur gardening is at a very low ebb. The gardens are cultivated in a way, and there are the periodical sowings and plantings, but they are carried out in an old rule of thumb sort of method, with no ambition to produce anything above the commonplace. A combination of gardeners changes all this, and it is characteristic of the best of gardeners that they are the men who are always anxious to learn more. They are not content with the old rule of thumb methods, but become alive to the advantages of growing the best varieties, of using suitable fertilisers, and adopting means of fighting the foes which hitherto had been allowed to increase unchecked. An interest is awakened in gardening such as was never known before, and the horny-handed members of the village society find out that by adopting the best methods of cultivating their cottage gardens and allotments they not only obtain produce fit for the show board, but they are doubly rewarded by the weight and quality of the vegetables for the supply of the household.

In addition to the annual summer show and the monthly réunions, there is the social side—the meeting of the professional gardener with the labourer, who is also a gardener, and the well-to-do amateur who gardens for a hobby, each and all imbued with a kindred spirit. Pleasing sketches might be drawn of such gatherings in the club room of the village, and no lover of gardening could take part in one without realising that horticulture owes much of its prominence to gardening societies.—G. H. H.

ODONTOGLOSSUM CRISPUM DAPHNE.

THE *Odontoglossums* that were honoured by particular recognition by the Orchid Committee of the Royal Horticultural Society during the second half of last year were not particularly numerous; they, however, made up for sparsity of numbers by excellence of quality. Amongst those selected for the award of merit was *Odontoglossum crispum Daphne* (fig. 13), which was exhibited at the Drill Hall by Mr. W. Stevens, gardener to W. Thompson, Esq., Walton Grange, Stone, Staffs. This was an exceptionally beautiful variety, and was quite distinct from any of its relatives. The sepals were pure white,

FIG. 13.—ODONTOGLOSSUM CRISPUM DAPHNE.

but the ground colour was almost obscured by an immense pale violet patch; the petals were paper white, with sparse spots of a similar colour to those on the sepals. The fimbriated lip was white with a prominent brown patch, while the throat was yellow.

LÆLIA AT ROSEFIELD.

It is perfectly safe for anyone to make the assertion that we are living in an age of specialism, and the genius who could turn his hand to anything and do it thoroughly is becoming conspicuous by his absence. In the arts and sciences, the professions and trades, we find individuals take up a definite line and follow it until their knowledge of it is practically unique. As it is in our daily vocations, so it is in our hobbies, and in no direction is specialism more rife than in the ranks of our amateur Orchid enthusiasts. There are general cultivators of course, but broadly speaking every grower has his particular pet, which he studies until he has its requirements to a nicety. Among the true Orchid specialists is Mr. de Barri Crawshay, of Rosefield, Sevenoaks, whose forte was at the outset *Odontoglossums* especially of the *crispum* section, but who some years ago added *Lælia anceps* to his stock. A few *Cattleyas* are grown with one or two other Orchids, but they are minors in the estimation of Mr. Crawshay, and from personal observation I should say they will eventually be ousted entirely.

While having these facts in mind it must not be thought that this gentleman has no knowledge of or capability of appreciation for other Orchids as well as for flowers and fruits. As a matter of fact he is a real horticulturist whose particular partialities find vent in two channels about with which he makes it his concern to know all there is worth knowing. It is not the time of the year for one to dilate upon the beauties of *Odontoglossum crispum* from a floral point of view, but one must admire the stout substance in the leaves and the pseudo-bulbs, and the rude glow of health in which they are clothed. These flowers have been spoken of in these pages in past days, and will be again, no doubt, if their owner maintain or improve the present high status of the collection. For the time, then, let us leave

them to the fostering care of Mr. Crawshay and turn our attention to the stock of *Lælia anceps*.

It is more than probable that many people have not yet realised the glorious beauty produced by a number of these plants when they are in flower, particularly of course when exceptionally choice forms are to the fore. Personally I can say that, though always an admirer of *Lælia anceps*, I was more than surprised with the plants at Rosefield. It is not one or two spikes that are to be found, but hundreds rising from the healthy plants, some having passed their best stages of beauty, with others just at perfection, and more still to come. And so it will go for many weeks to come. In the different types of growth alone there are several object lessons, and needless to state Mr. Crawshay has taken advantage of them. He now speculates on the results that are likely to come with flowers of this or that plant, and not seldom his suppositions are fully realised. There are small plants and large ones; imported stocks that have not yet proved their right to hold a permanent position at Rosefield, with many that are prime favourites which are never likely to lose their places even though superior varieties may and probably will come to the fore.

With a laudable view to artistic effect Mr. Crawshay has had the choicest of those flowering at the moment placed together at one end of the central stage in a span-roofed structure. The little group makes a most gorgeous display, and yet one which, with all its brilliance, is essentially refined, for in the beauty of colour and form of *Lælia anceps*, there can be found nothing coarse. Superb in every respect are Mrs. Crawshay and Crawshayana (fig. 14), as might naturally be expected with such varietal names as these. Then the flowers of Chamberlainiana and Amesiana must have a word of appreciation for the size and colouration in the first place, and for the exquisite hues in the second. The spikes of white rising amidst the lively colours of those named not only show off its own beauty, but emphasise the glory of its companions. Others named and unnamed are in flower or bud, and one or two may find their way to the Drill Hall in the days to come, in which case we may rest assured that they will be decidedly above the average standard of merit, as Mr. Crawshay is no believer in the exhibiting of plants or flowers that will not add credit to his name.

Just one other point and the pen must cease its working. This is in relation to the practice that prevails of naming every flower that opens, be it good, bad, or indifferent. On this Mr. Crawshay holds very strong opinion, and holds that none should be given a specific name that is not in some decided respect a step in advance—more particularly when the plant is to be publicly shown. This is the principle on which this grower works, and though he may and does give some forms fancy names it is because they have decorative value for home use, and are never shown as varieties of super-excellence. Would that others followed this excellent example. Though Mr. Crawshay has such a familiarity with the wants of his plants, and does much practical work amongst them, he will not grudge a word of congratulation to his gardener, Mr. Cook, who must be given a place in the foremost rank of *Odontoglossum crispum* growers in the country.

CYPRIPEDIUM INSIGNE AT THE WOODLANDS.

As years succeed years the gardener, be he amateur or professional, who carries on his avocation within the area of London smoke, has greater and greater difficulties to overcome. Moreover, every season finds the radius of the smoky fog fiend extending, until places which a decade ago were quite clear, now have visitations at all too frequent intervals. Thus it is that the probabilities of success in the cultivation of any kind of plants become yearly less, and the labour involved in insuring even moderately satisfactory results grows proportionately. Few indeed are the plants that will withstand the baneful influences of London fogs, which enwrap everything as in a mantle, and leave in their wake a filthy

slime on all stock out of doors, and a sediment on the leaves of plants under glass. These substances, of whatever their nature, exercise an undoubtedly deleterious effect as well on persons as on plants, and the London gardener of to-day sighs for the sweet pure air of the country, where his own life and that of his plants would be materially prolonged.

In no phase of gardening are the prejudicial effects of fogs more pronounced than in that of Orchid growing, and the spirits of many growers must often be damped when hundreds of flowers are spoiled, and the foliage of plants is seriously injured. These troubles have come to more than one grower during the past autumn and winter, and possibly none have suffered more than Mr. R. H. Measures of The Woodlands, Streatham, whose collection of *Cypripedium insigne* we had the pleasure of inspecting a week or two before Christmas. There was no difficulty in finding abundant evidence of the damage that had been done to the plants, as the leaves presented an appearance which until now has been quite foreign to them. Flowers have come, and ere yet they have shown their beauties have been destroyed by fogs. If these effects follow with flowers of such substance as *Cypripediums* one can imagine the disasters among the *Cattleyas*, of which we learnt from Mr. J. J. Coles, the gardener, hundreds quite failed to develop from this cause alone.

Notwithstanding all this, the magnificent collection of *Cypripedium insigne* was worth going many a mile to see, and we would not envy anyone the task of finding its superior. The number of plants closely approaches to five thousand, and if we take the very moderate average of six blooms to a plant we have the extraordinary total of nearly 30,000 flowers. This, we are convinced, is decidedly below the actual number, and fortunately they are not all expanded at one moment, but come in constant succession over a long series of weeks. The length of time during which they last is, as has already been suggested, materially affected by the external climatic conditions, and it is much

FIG. 14.—*LÆLIA ANCEPS CRAWSHAYANA*.

to be hoped that the autumn of 1900 will be more in favour of longevity than was that of 1899. Happily, neither Mr. Measures nor his lieutenant is likely to be disheartened, or we should have them packing their Lares and Penates and passing into districts more congenial to the plants, but less accessible to the interested visitor. "This has been," said Mr. Coles, "the worst season within my

experience, and has done damage to the plants such as I have never before observed."

After the remarks in the preceding paragraph having particular relation to the number of plants, we need frame no excuse for the omission of names. Not that the whole are named—indeed only a small moiety are so distinguished, and, needless to say, these are the cream of the collection. There is a wonderful variation in the colour and size of the flowers, while differences in the shape of the blooms and in the foliage are by no means uncommon. Every good form that is procurable finds a place at The Woodlands, and, as a consequence, what with these and big consignments of imported stock, the numbers are rapidly and persistently increasing. *Cypripediums* are not, however, solely confined to the insigne section, but comprise also hundreds of species and hybrids from various sources, as well as many that have been raised on the place. Needless to say some of these are extremely rare and valuable, and numbers of them are strikingly handsome. These, too, have suffered with the insignis from the untoward season they have just experienced.

Apart from the *Cypripedium insigne*, The Woodlands is world-renowned amongst orchidists as being the home of the finest collection of *Laelio-Cattleya elegans* in the world. For a number of years additions have been made, and extension is still in progress. Several of the forms are of surprising beauty, and it is seldom indeed that one can enter the house without finding something to admire beyond the handsome plants. Needless to say this is not exactly a time of plenty. *Laelia purpurata* again is largely represented, as indeed are practically all Orchids. *Odontoglossums*, *Cypripediums*, *Cymbidiums*, and others are planted out in various places, and luxuriate in the treatment to which they are subjected. *Phalaenopsis* have been a source of trouble in the fog, and their condition on one Sunday morning after a Saturday night fog was so bad that every leaf had to be immediately sponged, and even after such prompt measures some of the leaves were destroyed. *Cattleyas* and minor sections also have due attention, and the whole of them are thoroughly well grown.

Mr. Coles' charge, however, is not one of Orchids alone; on the contrary, there is a considerable amount of outdoor work to be done, particularly in the production of vegetables and flowers in abundance. Indoors it is mainly Orchids, but one house of fair size is completely filled with Carnations, mainly of the Malmaison section, whose condition proves that with the culture of these, as with that of Orchids, this quiet and unobtrusive gardener is perfectly conversant.—H. W.

CLIMBERS FOR COOL CONSERVATORIES.

In ordinary plant houses in which plants are grown for the embellishment of conservatories and other decorative work, it is not usually a wise plan to have creepers growing on the roof, for although at certain seasons they may not be inimical to the welfare of plants beneath, nevertheless there are times when they prove a great drawback to plant culture. In the case of a conservatory, however, the matter is somewhat different, as the majority of plants only make a brief stay in that structure during the time they are in full beauty, and the slight shade given by the climbers is often beneficial rather than otherwise. A roof lightly draped with attractive flowering plants also adds much to the general effect, and for this reason no conservatory can be considered complete without its quota of climbing plants.

In connection with their management, however, one point should be rigorously kept in view—viz., to keep the shoots thinly disposed, which is a far different matter from allowing them to form a dense thicket to the detriment of nearly all plants beneath; moreover, one good shoot thoroughly exposed will produce more and better flowers in a year than half a dozen when closely crowded.

The rose and white varieties of *Lapageria* are extremely popular, as the flowers are always useful for decorative work, and when the shoots are trained to the roof of a conservatory the pendulous flowers are displayed to advantage. If planted out in fresh loamy soil at the back of the hot water pipes, and given abundance of water during the growing season, they may be relied on to produce numbers of strong suckers annually when once the plants are well established, but they often need a little extra attention for a year or two to get them to start freely. Liberal syringings are of great assistance to *Lapagerias* during the growing season. Few insects attack them, the most troublesome being white scale, which should be thoroughly dealt with by sponging and syringing with an insecticide as soon as the slightest trace is observed. In order to keep the growth thinly disposed it is a good plan to remove some of the old shoots during winter, as with healthy plants there is usually not much difficulty in securing plenty of young growths, which ought to be regularly—yet loosely—tied in as they extend, otherwise they have a tendency to coil

round the trellis and get broken when disentangled. When planted on the south side of a house a light shade should be given during the summer.

Passifloras have few equals in their capacity to cover the roof of a large house quickly, and when the allotted space is occupied the shoots require thinning several times during the summer, or they will form a perfect thicket. When tying the shoots if a few moderately long ones are allowed to hang naturally below the trellis they have a very pretty effect when in flower. *P. coerulea*, though old, is still worth growing, as the beautiful markings of the flowers need close examination to find their true charm. *P. Constance Elliott* is, I think, the best white variety I have seen; it ought to be grown in every large conservatory. Two excellent deep red forms are *P. racemosa* and *P. Raddiana*. If these are planted near the white ones already named, so that the shoots may intermix, a fine effect is obtained. Good loam enriched with a third of decayed manure will grow all the greenhouse *Passifloras* well.

Hoya carnosa, though not one of the showiest of plants suitable for covering roofs or training under rafters, is certainly worth growing, as the wax-like pinkish white flowers are always admired, and form pretty and uncommon buttonholes. This plant is well adapted for a small conservatory. It succeeds in a pot, and requires a compost formed of peat and fibrous loam in equal quantities. During winter the soil should be kept dry, but not sufficiently so to cause the leaves to shrivel.

An old favourite, *Plumbago capensis*, still finds a home in many a conservatory; an ideal position for it is against a tall pillar near the centre of a house; the young shoots can then be allowed to grow at will, and in summer time will then form a wavy mass of delightful blue. Keep the soil dry during winter, and prune hard, are the only cultural details which need be given, as the plant is not in the least particular in regard to soil. For walls and rafters *Habrothamnus elegans* is a striking and floriferous plant. If planted in good loamy soil enriched with a third of manure, strong growths are made which produce fine pendulous clusters of flowers at the points. The best results are obtained by keeping the plants rather dry at the root in winter and growing hard in spring. It is, however, quite possible to keep them in steady progress throughout the winter. The variegated variety, *argentea*, is also highly attractive.

Ivy-leaved *Pelargoniums* are by no means to be despised as wall or roof plants. Strong growing varieties as *Souvenir de Charles Turner* and *Robert Owen* are seen to the best advantage when trained in such positions, as they require plenty of room to ramble, and the growths should, of course, be thinly trained. The only objection I know to their use as climbers is their tendency to become infested with green fly, which often necessitates fumigating a house when the other occupants are free from insects—a rather expensive proceeding.

All the strong growing *Fuchsias* make excellent rafter plants, and when once established they flower grandly year after year with comparatively little trouble, beyond watering and feeding freely during summer. When I visited the famous gardens at Chatsworth some twenty years ago the *Fuchsias* trained to the roof of one structure were a revelation to me, as I thought I had never before seen their charms displayed to such fine advantage. Few gardeners seem to be aware that the very useful *Asparagus plumosus* is an excellent greenhouse climber, which will thrive in quite a cool house throughout the year if planted in a border formed of loam and peat. The border should be watered as required during winter as well as summer; growth is then continually going on, and strong shoots are frequently sent up from the stool to replace any which are worn out though age. Where large quantities of this *Asparagus* are required for cutting, walls and roofs of cool houses should be covered with it, so that "armfuls" may be cut when needed.

Any climbing *Roses*, particularly such fine varieties as *Climbing Devoniensis*, *Alister Stella Gray*, *Climbing Niphetos*, *Climbing Perle des Jardins*, *Maréchal Niel*, *Reine Marie Henriette*, and *W. A. Richardson*, are well known to be admirably adapted for training to the roofs of greenhouses and conservatories. The selection above given, is, I trust, varied enough to suit the tastes of all, and those who have a house large enough to enable them to plant the whole collection should be able to produce—during the spring and summer months—a wealth of varied and beautiful flowers to meet the upturned eye, which, for a time, is raised from the pleasing task of viewing the floral gems arrayed beneath. With beauty above, below, and all round, who would not be happy in a well-managed conservatory?—H. D.

SNOW PROTECTION IN FORESTS.—Snow is often very injurious in Pine forests by breaking down and crushing the young trees, especially if the snow is wet when it falls. This injury is difficult to guard against, but in forest planting it is well to remember, says a transatlantic contemporary, that very tall thin trees suffer most. Choose those whose growth in diameter and weight keep better pace with their height. In many regions snow is very useful in protecting the soil and young trees, so that the harm it does is usually more than counteracted by its benefits.

REMINISCENCES OF AN OLD FLORIST.—No. 3.

It may well be imagined what a change it was from the lovely valley of the Dargle, with its rushing river and wooded slopes, to the cockneyfied seaside resort of Ramsgate; from a good sized house with its pleasant surroundings of garden and lawn, to a cottage whose back garden was not much larger than a tablecloth; and how little likely it seemed that I should ever take up the subject of horticulture again. Yet after about fifteen months' residence there I removed to Deal, with which place my name has since been associated. One or two things, however, concerning Ramsgate may be mentioned. It was almost with despair that I looked round what was called my garden. I had a border about 18 inches wide, and I thought I might fill it with something, so I tried *Verbenas*, and very soon had it gay with some of the older varieties of this charming flower. I had also a few plants in pots of a Lily that was very scarce then, but is now plentiful enough—*Lilium speciosum*, so that friends used actually to ask to see my flowers!

A somewhat amusing incident occurred while there. A friend, who had travelled with me on the Continent, came to see me. The plan then was to send passengers' luggage up to the various residences, marking them accordingly. They did not put the whole address on, whether terrace, place, or so on; but just "1, Vale," my house being 1, Vale Place. My friend was asked where he was going to, and he told the porter; the man replied, "Then that is one whale for you, sir." "Well," said my friend, "that is the largest order for fish I ever gave." However, no matter of horticultural interest was connected with my residence at Ramsgate.

But how came I to move on to Deal? In a curious way I had gone over to the reopening of a church at Canterbury by Archbishop Sumner. He had not long come to the diocese, and the clergy were mostly strangers to him. I had just been corresponding with him, saying I wished to remove; so when his chaplain told him who I was, he said, "I should like to speak to Mr. D'Ombrian," and in his affable and courteous way he alluded to our correspondence, and said something about a curate being wanted at, as I thought he said, Deal, and said so to him. "Oh, no," he said; "I did not say Deal, but by the Dean." After a little more conversation, as I was rising to go, he said, "By-the-by, you mentioned Deal; there is a church vacant there if you would like to have it." My surprise may be imagined. I asked if I might have time to think over it. He replied, "Oh, yes;" and most of my friends advised me to accept the offer, which I did, and the mistake of that one letter led to the whole alteration of my life; on such little matters do often the tenor of our lives depend. I knew little of Deal by previous report; I went over to see it, and determined, notwithstanding the advice of my friend the late Canon Hoare, who was then my rector, to accept the offer, although the stipend was a small one, and the work I knew was very heavy. This was in the year 1849, fifty years ago; and I have to record my experiences during that lengthened period.

It must be remembered that I kept no diary whatever of results connected with gardening, and therefore there will be no chronological order in what I have to tell. Some of the most noticeable events, of course, I remember the date of, but the great majority will be only vague guesses, somewhat approximating the truth. One of the things that most struck me at this time was the vast difference between the nursery establishments of London and Dublin. I do not know what they may be in the Irish metropolis now, but at that time there was not one which was better than those in any third-rate English town. Orchids were unknown, and, indeed, expensive plants of any kind found no place. It may well be imagined, then, how astounded I was at the grand establishments of James Veitch & Sons at Chelsea, Low & Co. at Clapton, Williams and Son in Holloway, W. Bull of Chelsea, and many others. Equally astonishing to me were the high prices given for new plants. It is no exaggeration to say that many a plant sold for more than its weight in gold, and several of the collections of amateurs were valued at thousands of pounds. Since those early days of what we may call the Orchid mania, when a single plant was sold for between £200 and £300, there have arisen various establishments, containing house after house filled with the choicest productions of various kinds, and affording a feast which no other country, I believe, could furnish.

There were also other flowers which were then appealing to the taste of the amateur, and amongst these was the *Chrysanthemum*, and numerous were the pleasant pilgrimages I paid to that home of the flower in those days—the Versailles Nursery of Mr. John Salter of Hammersmith. On many a dreary November day I wended my way to this nursery to discuss the merits of the new varieties of incurved flowers which were then all the rage. I well remember the introduction of the little Chusan Daisy, as the Pompons were then called, and also that of the Japanese variety, which were at first more scoffed at than welcomed by the admirers of the older types. No one could, of course, then have foreseen the wonderful revolution which these

were to make in the development of the flower, and indeed it must have astonished the growers themselves. Take, for example, a bloom of the old Red Dragon or Meg Merrilees, and compare them with those of Phœbus or Vivand Morel, and it will be found very difficult to believe that they are developments of the same flower.—D., Deal.

ORCHARD AND GARDEN PESTS.

THERE are few cultivators who have not a great abhorrence to the presence of pests in their gardens, and many persons go so far as to say that compulsory measures ought to be taken to compel the careless and indifferent gardeners of all sections to adopt such preventive and remedial measures as may be required to keep their crops and gardens clean—if not for their own sake, for that of their neighbours. It is hard on a clean, energetic, and thrifty gardener to have as a near neighbour one of the careless, indifferent, and happy-go-lucky sort, who does not see the desirability of destroying weeds till they are seeding, or diseases and insects till his plants are smothered in filth.

Possibly men of this calibre have an idea that such a state of things balances the production and demand, and thereby enables the growers to obtain better prices, as I note a colonial pomologist writes to the effect that he considers the codlin moth the fruit growers' best friend, for without it he says the markets would be everlastingly glutted, and the Apples worthless. Even in the face of this argument, however, I prefer clean, healthy trees, and perfectly sound fruit. Many people object to Acts of Parliament which compel them to spray and bandage as interfering with their so-called liberty. They cannot do as they like with their own. Why, might I ask, should they, if it is detrimental to the interests of their neighbour, or to the development of an industry which is for the common good? Such measures would not be passed for those who do their best to have clean gardens, trees, and crops, but even these would have to give the inspector all the necessary information, and show him over the orchard or garden at a considerable cost in the shape of time, simply because of the black sheep who have spoiled the flock.

An intimate friend who grows fruit largely in New Zealand says that "economic fruit growing cannot be a success in that colony until men with experience and capital enter the industry on an extensive scale, which no one is prepared to do so long as our laws allow the careless and lazy orchardist to breed all kinds of insect pests that invade all orchards in the district, and make profitable fruit raising impossible." In 1898 the colony paid for imported fruit something like £71,000. They have had an Orchard and Garden Pests Bill before their House of Representatives, but whether the Bill has yet been passed I cannot say. The main objects of the Bill were (1) To prevent the introduction into New Zealand of insects and diseases affecting orchards and gardens; (2) to provide for the eradication of such pests as infest the trees; and (3) to prevent the spread of any such pests.

The pests mentioned in this colonial Bill are the Mediterranean or West Australian fruit fly (*Halterophora capitata*), San José scale (*Aspidiotus perniciosus*), Queensland fruit fly (*Tephrytes tyroni*), Vine louse (*Phylloxera vastatrix*), American blight (*Schizoneura lanigera*), Apple scab (*Cladosporium dentriticum*), codlin moth (*Carpocapsa pomonella*), and the mussel scale (*Mytilaspis pomorum*).

In my opinion there is nothing unreasonable in a Bill of this nature. Relative to the first clause, I would ask what can we in England do towards preventing the introduction of insects and diseases? What about the *Chrysanthemum* rust and the American blight? Are they introductions? If so, what measures could have been taken to prevent their introduction into this country? Can we adopt any means to prevent the introduction of other insects and diseases? Is the question worth our consideration? If so, may we have the opinions and suggestions of the many experienced contributors of the *Journal of Horticulture*? To eradicate and prevent the spreading of garden pests many methods are in vogue, the majority of which would no doubt if persistently followed prove efficacious.

The San José scale is evidently very prolific if, as one large fruit grower states, that "one female alone can produce 5,600,000,000 descendants in four months." I trust we may never have personal proof of its rapidity of propagation. Local influences have unquestionably much to do with the spread and development of various insects and diseases. Good cultivation is an important factor in keeping insects and diseases at a minimum, for without this spraying bandaging and other methods would be of little use. I am acquainted with a New Zealand fruit grower who obtained in 1898 13s. per case of 48 lbs. for Apples whilst the average price was 5s. 6d., and this was very largely, if not solely, due to good cultivation.

The sum total of cleanliness in our gardens, of productiveness and of success generally, may be condensed into the one word—cultivate—which should ever be the fruit grower's watchword.—S. II.

CYCLAMENS AND PRIMULAS AT READING.

It is not every year that the fates are sufficiently kind as to allow me to visit Reading during the dull winter days, to be cheered and invigorated by the sight of the Cyclamens and Primulas in Messrs. Sutton & Sons' Portland Road Nurseries. Come when it may the opportunity should be seized to go, for the spectacle presented by thousands of plants in 5-inch pots is one that will not readily be forgotten. There are no huge plants, but all are compact and sturdy, and in the best possible condition to perform the particular function for which they are grown, that is seed bearing. They are not required to make huge growth, but to develop all the essential organs to the highest state of perfection, and thus insure a bountiful harvest of seeds. Under other circumstances larger plants would be more advantageous, but not in this case, and those who desire size may rest assured that those which thrive at Reading will flourish elsewhere if their particular requirements are carefully sought and provided for.

Thousands of handsome little plants occupy the structures erected for them, and each winter finds a beautiful display, something like its predecessors, and yet somewhat different, for new forms or colours are ever pushing to the fore. This is more particularly the case with respect to the Primulas, which always show advancement. With Cyclamens, however, such a state of excellence has been attained to, that the difficulty of forging ahead becomes greater and greater, and a variety to receive a special name must literally be without fault. There are amidst the Reading strain of *Cyclamen persicum* colours that were undreamt of a few years ago, and with this form of beauty has been retained the floriferousness and the splendid marbling of the leaves, which are found in the type. Take for example *Salmon Queen* and *Vulcan*, each in its way perfect. The flowers are of wonderful substance, faultless in shape, and each in their respective colours unique. Each produces immense numbers of flowers, and in both instances the habit is excellent. What more desirable attributes could be desired? "Fragrance" someone may say; but let them have patience, for there are indications that even this will come eventually.

These are by no means the only colours in the *persicum* section, but they are chosen as the best from the writer's point of view. Those who would doubt or disagree can go to Reading and decide by personal inspection; they will be heartily welcomed, and will return home the wiser for what they have seen.

The dividing line between the *persicum* and the *grandiflorum* section is very clearly marked, and each has its ardent admirers, who see far more beauty in their respective favourites than they do in any others. Here we find stronger growth, stouter and bigger leaves, and bolder flowers. The votaries of the *grandiflorum* type pin their admiration mainly to the size of the flowers, as the leafage is not so handsome as in the smaller flowered group. In this respect, however, advance can readily be seen, as it is not so very long ago that the leaves possessed no particular beauty, whereas many of them now are considerably marbled. Perhaps Messrs. Sutton & Sons will some day give the horticultural world a *Cyclamen grandiflorum* with the freedom of flowering and the charmingly marked leaves of the smaller section.

Of all the colours amongst the *grandiflorum*s I must still place the pure white as prime favourite, with the white on a crimson base as a wonderfully close second. These two occupy the same position in my regard as the two named in an earlier paragraph. There is no garish beauty, but rather have they a simpler charm, which appeals with greater force than the more effective crimsons, purples, and others. Naturally enough these have their admirers, as must have all such excellent flowers, but I speak now from a purely personal standpoint. There can certainly be no two opinions as to the value of Cyclamens for Christmas flowering, and hundreds of gardeners would miss their presence, and have difficulty in finding an equally good substitute for various purposes at the festive season. It is still an open question as to whether the curious papilio section will ever run level with the others for popularity. So far they are decidedly in the rear, but the tide of fashion may turn in their favour, when they will quickly range up in the front rank.

In the houses devoted to the Primulas there are many varieties to admire amongst the single, the double, and the stellata sections. The plants are arranged in such a manner as to call forth the highest praise, for they are staged in large batches of colour. For instance, in one house are some hundreds of *Crimson King*, and they rivet attention and form a lasting impression. These, indeed, are the results that accrue from seeing several of the varieties, some of brilliant hue, others owing their charm to chasteness of shade, while still more range between the two. There are varieties with identical flowers and different foliage; in the one case it will be plain and in the other Fern-leaved. Both have beauty, and show their flowers up in a peculiarly distinct manner. The Reading Blues are well known for their high quality, as are such whites as *Pearl* and *Snowdrift*, which now require no cards of commendation. A new break, of which *The Duchess* may be taken as typical, is very beautiful; the flowers are striking, with their zone of brilliant rose round the eye, and this encircled by white with an attractive rose suffusion. There are other new colours, too, but of these more will certainly be heard in the future.

The Star Primulas have been accorded a great meed of admiration of late years, and they may now be expected to maintain their position.

The flowers have not the size, substance, or form of the *sinensis* section, but they are of more graceful habit, and branch and flower with remarkable freedom. These, too, are becoming more diversified in colours every year, and have a beauty that is quite their own.

Amongst the semi-doubles and doubles there are the well known Reading varieties that may be taken as types of excellence in their respective shades. But to these must be added the newer ones, of which *General French* will be regarded as the most important. This has received an award of merit from the Royal Horticultural Society, and this alone is a true hall mark of excellence. It is a very deep rich crimson flower, freely produced by a compact growing plant, having elegant leaves. Many others might and perhaps ought to be particularised, but time forbids that more shall be written save to advise those who have not been to Reading to go as soon as possible, so that they may lose none of that charm and beauty which were so much admired by—R. H. R.

REMARKABLE in extent and variety as was the fine collection of Primulas shown by Messrs. Sutton & Sons of Reading at the Drill Hall on the 9th inst., and so happily helping to save the meeting from failure, yet no comparison could well be instituted between that exhibit and the collection of these beautiful winter flowers seen in their home, the long span houses at Reading. It is not merely that one may see there so many more plants, but under the clear bright light the true beauty and excellence of the flower is so much more fully manifested.

As the primary object of the firm is to obtain seed, sowings are not made until July, and the plants are all in 48's. Thus whilst so beautifully in bloom thus early in January, they will increase in floral beauty as the year extends and light increases, so that the considerable work of pollination which has to be in every case artificially performed is materially assisted. February and March are important months for the performance of this work.

The Reading Primulas have been written about continuously, but those who may have seen them as I have for many successive years still find them to be each recurring winter wonderfully attractive. No doubt much of this attraction is due to the great stocks of plants seen, each one so true in form, colour, size, and everything. Then the clear light aids so much to display the colours of the flowers, and the admirable culture bestowed helps also to one's appreciation.

Whilst every year shows some advance in form, variation, or colouring, the present season seems to have been peculiarly rich in that respect, for there are several singularly charming novelties seen that must in time become exceedingly popular, and will, when they can be put into commerce, be in great demand. Certainly *The Duchess* is a great beauty. The flower stems are stiff and erect, habit excellent, flowers large and finely fringed, and the colour white, but having round the eye a ring of intense rosy red, that shades off into the white indefinitely. This is indeed a beauty, and most distinct. Then there is one that, because even more delicately coloured, though in all other respects alike, that I even preferred to the *Duchess*; that, so far, has no name, but it will have to be "Princess" at least. The ground of the flower is flesh white, verging to a ring round the eye of soft rosy flesh; a singularly charming flower. Another of great beauty has flowers of vermilion round the eye, shading off to pink. There is, too, a gloriously rich magenta, with lemon eye; one of singularly deep solid blood crimson; another of a heavy plum blue; one having a deep peach centre, shading off to pale pink; and another having bright red centre, shading off to rose.

The old Reading Blue has been intensified, whilst by crossing that on to a good white with pale green stems there has resulted a very pleasing Cambridge blue, a shade that is very refined. That brilliant heavy hued *Crimson King* is indeed a superbly coloured variety, being in striking contrast to *Snowdrift*, the pure white form which again is flanked by the crimson on the Fern leaf, the colour of the flowers in this case seeming to be much intensified. Then *Pearl* is another beautiful pure white on pale green foliage. But singles are in every direction remarkably varied and beautiful, yet cannot be all noted.

Still a word is due to the charm as winter decorative plants of the star or stellata section, large quantities of which are here in variety. There is the original form, then comes a greatly improved white on intensely dark foliage, and a third white on pale green foliage, the habit being more compact. There is also a carmine or pink flowered section, all abundantly blooming. From out of the entire collection some improved forms or possibly improved forms have been selected, but the merits of pink flowers will not outweigh the absence of the graceful branching pyramidal habit if that be lacking.

The semi-doubles are in great abundance. Blood red, pink, white, carmine, carnation flaked and splashed, blue, and others are all as fine and as effective as Primulas well can be. One long lean-to house devoted to trials will soon possess special interest. Here are grown in large 60-sized pots some plants of every stock of Primulas in the hands of the firm. It says much for the excellence of the culture given that out of the several hundreds of these plants here every one is as good as the other, so that the trial will be a perfect one. Of course these are from a rather later sowing than were the many stock plants in larger pots. But it will enable visitors to discern a week or two later how much floral beauty such small plants can produce.—A. D.

LATE SPRING PLANTING.

I CAN assure Mr. Pearson that I am fully alive to the difficulties he speaks of on page 24 as to getting all planting done at the most suitable time, and not once, but many times have I used the very arguments he has when my employer has asked me to write and "hurry up" the nurserymen who were entrusted with his orders; and there has not been a week since last October that I have not been planting more or less when the weather has been open. I have planted some scores of acres within the last four years with a rather small staff of men, and Mr. Pearson knows, and so do I to my cost, that this cannot be done in a few weeks; but I say, as I did before, that the two seasons I mentioned are the best of all for the purpose, and can with perfect assurance advise anyone who is planting to make the utmost use of them. It was no hobby that I was riding, and it is not yet ridden to death.

I should like to say, too, that the very trees and shrubs I mentioned were sent more than fifty miles by rail, and not shifted from one part of the garden to another. This, I think, quite refutes your correspondent's argument that "this"—i.e., spring planting—"is of no use to the ordinary planter, who has to procure his plants from a distance." But I could give many such instances if need be, and can point out to a single row in certain places where planting has been done in the same field at correct and incorrect times.

I quite agree with all Mr. Pearson says respecting the proper cultivation of the ground both before and after planting; and here again I could, if need be, a tale unfold. But the fact still remains that the best of all times for planting are those named, be the nurseryman never so busy.—H. R. R.

I THINK it is generally understood that autumn planting, say as soon as the leaves have fallen, is the best time for fruit trees and Roses. As Mr. Pearson points out, however, it is not so imperative to plant early as some growers would have us believe. As Mr. Pearson rightly states, the future growth and ultimate success of fruit trees is almost entirely a matter of management, first in planting when the soil is in proper condition, then how they are planted and of what the after care consists.

To insure success the planting and after management must go hand in hand. It would be useless to plant well and be inattentive to the wants of the trees afterwards. Neglect of the retention of moisture in the soil by mulchings, or simply stirring the surface soil and allowing it to crack, are the points which would hamper the progress of any tree, no matter how well it might have been originally planted. Personally I should prefer to plant an Apple tree as late as the first week in April rather than not at all that season. With intelligent care abundance of new roots would be made, and the tree should be thoroughly established by the following November, even if it did not make much growth.

My aim with newly planted Apple trees, for instance, is to manage them in such a way that when November again comes round many of the newly made shoots require 2 feet of growth pruning away. Such trees have without doubt a sufficiency of the right sort of roots and vigour, and it would not be unreasonable to look for a crop of fruit in one and a half year from the time of planting.—E. MOLYNEUX.

APPLES AND FROZEN WATER PIPES SPLITTING.

It is rather amusing to ordinary mortals to read the conflicting remarks on the above subject of "A. D." and "H. Richards," two correspondents who contribute largely to the literary food of your readers. I do not profess to belong to the angelic host to which "A. D." refers on page 34, nor is it necessary for me to attempt to render any assistance to "A. D.," as his position in this matter is beyond dispute.

My object in penning these notes is to record an incident that happened in the winter of 1874, and, which I think substantiates the view or "suggestion" of "A. D." in relation to the splitting of Apples. In the year referred to there was a quantity of Apples stored in a room over a coach house facing due north. On one night the thermometer registered 24° of frost, and, as there was not sufficient means for excluding the cold air, the whole of the fruit was frozen quite hard.

So long as the frost continued the skins did not present a ruptured appearance, but shortly after the thaw set in the largest fruits burst their skins, and the whole of the frozen fruit was utterly spoiled. The water in a number of bottles that were used for bottling Grapes in the same room was frozen into solid lumps of ice, with the result that every bottle was burst. The damage, however, was not caused in either case by the thaw but by the expansion of the frozen water. Frozen water is lighter than water in a liquid state, otherwise how could it float on the surface?

I would suggest to "H. Richards" to make the following simple experiment. Fill a jar, such as is used for holding marmalade, up to the brim with water, and expose it to 15° or 16° of frost, when if the result is similar to what I have had, he will find the frozen water has risen considerably above the top of the jar, and in addition he will discover,

when the thaw sets in, that the jar has been split and the bottom forced out, which I think is sufficient proof that frozen water increases in bulk.—W. N., *Holmes Chapel*.

I CANNOT say that I was pleased with "A. D." when I read his remarks on page 34. But let that pass. By a printer's error, or from some other reason, "cold" was printed instead of "cooled," and despite the allusion to the Polar regions I must, with all deference to "A. D.," maintain that I was right. I know well enough that ice will break pipes, but I also know that heat applied to a frozen pipe has the same effect though that pipe has been frozen for weeks without bursting.

But really this has nothing to do with Apples splitting in "A. D.'s" case, as the room in which he kept them he describes as cool, and simply to prove that his theory was not the correct one I sent the note referred to. "A. D.'s" question as to whether I have seen pipes burst by having the contained water heated is altogether wide of the mark. Engineers always leave vent for expansion, but if it interests "A. D." to know it I have seen the water run over the top of a feed cistern when only very slightly heated, and that is quite proof enough for me that water does expand when heated and contracts when cooled, no matter what it does when it freezes, and ceases to be water in a mechanical sense. To cavil, however, at such a simple matter is only to confuse the issue. At all events, such a homely instance as the baking of a thin-skinned Apple such as "A. D." describes will show whether the said Apple will split under the influence of heat or not. I think I have seen them do so.

"Ret Rail" is really a very funny man when he likes, and the game of filling bottles and freezing them is an excellent one but slow. Bothy men have played it in their young days, so doubtless have college students, and personally I may say that if ever I meet "Ret Rail" I can show him the results of the fun upon my own person.

And now may I suggest a little experiment to "Ret Rail?" Let him fill a common fish or tobacco tin with cold water and place it in quite a level position over a gas jet. Light the gas and keep the surface tension of the water broken by means of a pin or a pencil, and note how long it will be before the heated water runs out. This will not endanger life or limb.—H. RICHARDS.

THE SALE OF POISONS.

IS AN AGENT A SELLER?

IN the Queen's Bench Division on Wednesday, January 16th, before Justices Grantham and Channell, the appeal, *Pharmaceutical Society v. White*, was heard. It was an appeal by the Pharmaceutical Society from the decision of the County Court Judge of Worcester. Mr. Crump, Q.C., and Mr. Grey appeared for the Society, and Mr. Cavanagh appeared for the respondent.

Mr. Crump said this was an appeal from the learned County Court Judge by way of an appeal in an action brought to recover a penalty under the Pharmacy Acts of 1852 and 1868. The action to recover the penalty was brought in the Worcester County Court, and the Judge decided in favour of the defendant, that he had not been guilty of an offence under the Acts. Section 15 of the Act of 1852 provided that any person, not a duly qualified chemist, who should compound or sell any poison should be liable to a penalty of £5.

The respondent, Mr. White, was a florist carrying on business at Worcester, and he sold a weed killer containing arsenic, which was one of the poisons mentioned in the first schedule of the Pharmacy Act. Mr. White admitted that he sold the weed killer, he admitted it contained one of the scheduled poisons, but said that in selling the weed killer he was acting as the agent of the Boundary Chemical Company, which carried on its business in Liverpool. He would take the order, take the money, and give a receipt, but he did not keep the poison in stock. When he received the money he sent the order on to the Boundary Chemical Company at Liverpool for them to execute, and the company would deliver the weed killer to the purchasers from White. Mr. White made a profit in the transaction. The learned County Court Judge found that Mr. White was not the seller, that he was selling as agent for the company in Liverpool, and not for himself, and consequently he was not a person within the meaning of the section of the Act. He (Mr. Crump) submitted that Mr. White was as plainly as as possible the seller of this particular poison. The Act was for the protection of the public.

Mr. Justice Grantham, without calling upon the other side, said he had no doubt that in this case the County Court Judge was right. White was not the person who was managing the sale; he was merely the conduit pipe to introduce the buyer to the seller. Mr. Justice Channell concurred, and the appeal was therefore dismissed.

Mr. Crump asked for leave to appeal, as the case was very important to the Pharmaceutical Society. They considered there was a new means of selling poisons without incurring liability.

Leave was given to appeal on certain terms.

SEED DISTRIBUTION IN AMERICA.—The Department of Agriculture began its distribution of seeds a little earlier this year than last, forwarding them south at the beginning of January. This year the seeds for distribution to all parts of the country will consist of 13,000,000 packets of vegetable seeds, 1,560,000 of flower seeds, besides field and lawn grass seeds.—("Washington Post.")

Recent Weather in London.—The weather in the metropolis during the past few days has kept very mild and unseasonable. On Sunday it was wet almost the whole of the afternoon and evening, the downfall being very heavy at intervals. On Monday it was very dull, but except for a few small drops no rain fell. On Tuesday the conditions were practically the same as on the preceding day. Wednesday was wet at intervals.

Weather in the North.—The two weeks ending 22nd inst. have been marked by very variable weather. Occasionally there has been a slight frost in the morning, never exceeding 3°. Snow has fallen, but to no great extent. Sleety showers and rain have been frequent, and some of the nights exceedingly wet and boisterous. The 18th was perhaps the finest day, but the following was extremely wet. Sunday was showery, the night tempestuous, and a high westerly wind continued throughout Monday.—B. D., *S. Perthshire*.

Continuation School Gardens.—Mr. John Ettle, county instructor in gardening for the Somerset County Council, sends us a report, showing that 119 educational plots were cultivated by youths under skilled guidance in the county last year. The silver Banksian medal of the Royal Horticultural Society was granted to the worker of the best plot. The Council of the Society allowed Mr. Ettle to purchase the medal, "thus forming a precedent, as the rule has been only to supply medals to affiliated societies."

Isle of Wight.—The annual meeting of the Isle of Wight Chrysanthemum Society was held at Newport on Saturday last. Dr. J. Groves, B.A., J.P., presided over a small attendance. Mr. C. H. Cave, Honorary Secretary, presented a financial statement of the affairs of the Society, which showed a very small credit balance; insufficient to carry on the exhibitions in the future. Therefore, after a lengthy discussion, it was decided to wind up the affairs of the present Society, and to call a public meeting with a view to establishing a new Society.—S. H.

Hessle Gardeners' Societ —There was a good attendance of members at the fortnightly meeting of the above Society, held on January 9th. The lecture for the evening was on "Plant Life," illustrated, by Mr. Knight, Pearson's Public Park, Hull. It is worthy of notice that the lantern slides for the purpose of illustrating the scientific remarks were of Mr. Knight's own production, and were deserving of great praise. The entertainment was highly instructive. Votes of thanks to the Lecturer and Chairman terminated a thoroughly enjoyable evening.—J. F. D., *Yorks*.

Death of Mr. Blackmore.—We regret to announce the death of Mr. R. D. Blackmore, the novelist, which took place on Saturday at his residence at Teddington. The deceased was a son of the Rev. J. Blackmore, and was born at Longworth, Berkshire, on June 7th, 1825, so that he was in his seventy-fifth year. He was educated at Blundell's School, Tiverton, and was a scholar of Exeter College, Oxford, where he graduated B.A. in 1847, taking a second class in classics. He was called to the Bar at the Middle Temple in 1852 and practised as a conveyancer, but he soon began to devote most of his time to literature, varying his pleasures in that direction by fruit growing, a pursuit in which he took an immense interest. Mr. Blackmore was a connoisseur in Pears, and grew an enormous number of varieties. Many of these were quite useless for commercial purposes; and yet because they did not "pay" he was apt to write letters to the "Times" against fruit culture generally as a profitable industry. He did not perceive that the most successful growers proceeded on exactly opposite lines to himself, namely, in planting many trees of a few wisely selected varieties, instead of one or two trees of as many varieties as he could obtain or find room for. He had quite a museum of Pears, interesting but unprofitable, and could happily afford to indulge in the luxury. Mr. Blackmore was a good judge of the quality of fruit, and was at one time, in the eighties, a member of the Fruit Committee of the Royal Horticultural Society. The late Dr. Hogg embodied some of his experiences in the "Fruit Manual."

The Driest Spot on Earth.—The reputation of being the driest spot on earth is claimed for Payta, in Peru, a place about 5° south of the equator on a coast that has risen 40 feet in historic times. According to a contemporary, Professor David G. Fairchild, a recent visitor, reports having reached there in February just after a rain of more than twenty-four hours, the first for eight years. The average interval between two showers is seven years. Sea fogs are common. Of about nine species of plants noticed, seven were annuals, and their seeds must have remained dormant in the ground for eight years. In spite of the lack of rain, the long-rooted Peruvian cotton is grown in the dried-up river bed, furnishing crops that yield subsistence to the natives.

Gardening Appointments.—Mr. Charles Young has been appointed gardener to Eustace A. Smith, Esq., Longhills, Lincoln. Mr. Young belongs to a good gardening family, of which his brother, Mr. Arthur Young, the competent head of Witley Court Gardens, is the senior representative. Mr. W. P. Bound, for the past two and a half years gardener to Mrs. Leveson Gower at Bill Hill, Wokingham, has been appointed head gardener to J. Colman, Esq., Gatton Park, Reigate, Surrey, in succession to Mr. W. King, who died recently. Mr. W. J. Blake succeeds Mr. Bound at Bill Hill, Wokingham. In the place of Mr. Whitaker who has resigned the position of head gardener at Crewe Hall, Mr. Fenner, who has been head gardener to the Right Hon. the Earl of Crewe, at Fryston Hall, Ferrybridge, Yorks, has been appointed, and has now taken over the charge. Those who know Mr. Fenner will be pleased to hear of the appointment.

Royal Meteorological Society.—The annual meeting of this Society was held on Wednesday evening, the 17th inst., at the Institution of Civil Engineers, Mr. F. C. Bayard, L.L.M., President, in the chair. The Secretary read the report of the Council, which showed that the most noteworthy event in connection with the Society had been the removal of the offices and library from 22, Great George Street, to new rooms at 70, Victoria Street. This step was rendered necessary by the acquisition of the former premises by the Commissioners of Her Majesty's Works and Public Buildings for the erection of new Government offices. Mr. F. Campbell Bayard, in his presidential address, discussed the meteorological observations made at the Royal Observatory, Greenwich, during the fifty-one years, 1848-1898, and brought out in a novel way many interesting features in the variability of the various observations of the barometer, maximum and minimum temperatures, relative humidity, direction of the wind, and rainfall. These were shown in a diagrammatic form on the screen by means of a number of lantern slides. The address was also illustrated by various views of the Royal Observatory and of the instruments employed. Mr. G. J. Symons, F.R.S., was elected President for the ensuing year.

The Richmond and R.H.S. Joint Exhibition.—Great as is the attraction afforded by the Temple Flower Show at the end of May, the two days' exhibition arranged for the present year in the Old Deer Park by the Richmond Horticultural Society and the Council of the Royal Horticultural Society, should prove to be a very formidable rival in attractiveness to the first named show, as it will be held at the end of June, and in the fine area at Richmond mentioned, where the surroundings are essentially picturesque and rural, where there is ample room and fine expanses of verdure, overhanging trees, and, in sunshine, pleasant shade, with undoubtedly a grand exhibition, for it is certain that on so auspicious an occasion the many habitual exhibitors at the R.H.S. meetings will support the national society in this new venture. Few towns near London, and it is not more than eight miles from Charing Cross, are so easily reached as Richmond. Lines of rail from literally all directions centre upon it, and therefore it can be most easily reached. The Deer Park is midway between the town and Kew Gardens. The beauties of Richmond Hill attract on the one hand, as do the botanical treasures of Kew Gardens on the other, whilst the silvery Thames flows so majestically along on the margin, enticing all lovers of aquatic life to disport themselves on its waters. All R.H.S. Fellows' and privilege tickets admit free to the Show on each of the days of the Exhibition, the 27th and 28th of June, and a great luncheon has been arranged to which all members of the Committees will be invited. Of course the respective Committees will sit as usual, and it is hoped find ample work furnished them. This gathering will not take the place of any of the Drill Hall meetings, but will rather be an extra; the conditions, however, under which it will be held should make it to resemble rather an enjoyable holiday outing than one of the stereotyped character. With fine weather the gathering should be a great success.—WANDERER.

The War and Cape Fruit.—"Tis an ill wind that blows no one good," and if, as it is said, there is a likelihood that, in consequence of quantities of Grapes and Peaches being held back at the Cape for the use of the wounded soldiers, the supplies of these two fruits will fall below the average, it will be good news for home growers. It is expected, says the "Rural World," that there will be a run on late English grown Grapes, and, moreover, that the prices asked and obtained will be uncommonly high. Should this be so, it will in a small measure be some recompense for the comparatively low prices to be obtained for home-grown produce when foreign supplies are plentiful.

Croton inimitabilis.—This Croton is so intensely brilliant in colour as to call forth admiration from anyone seeing a well-grown specimen. Not so vigorous a grower as that well-tried sort Queen Victoria, it makes a choice exhibition specimen, and far surpasses it in the rich glowing crimson shades of its foliage. We have at the present time such wonderful variety amongst these charming foliage plants that it is almost a matter of wonder that so few varieties figure at our exhibitions as specimen plants. To those who can accommodate and grow specimen plants the idea might well be considered with much benefit to themselves and a great gain to the public at large. The above-mentioned variety will most certainly count to any exhibitor.—R. P.

Ipswich Gardeners' Association.—A public meeting of those interested in horticulture was held in the Ipswich Town Hall on the 15th inst. to consider the suggestion made by Mr. Close at the annual meeting of the Horticultural Society, that a mutual improvement society be formed. There was a large attendance, most of the local nurserymen and gardeners being present. The proposition to form a society, to be known as the Ipswich and District Gardeners' and Amateurs' Mutual Improvement Association, was carried unanimously. A committee of nine, consisting of three each, nurserymen, gardeners, and amateurs, was appointed to frame rules and regulations. Mr. W. E. Close, Holy Wells Garden, was unanimously elected Hon. Sec. Forty-seven gave in their names as members at the close of the meeting.

The Sale of Poisons.—At a meeting recently held in Scotland, Mr. M. Cuthbertson, nurseryman, of Rothesay, asked the Lord Advocate if he would be prepared to support a Bill in Parliament making it legal for seedsmen and other agents to sell poisonous preparations such as sheep-dips, insecticides, and weed-killers. In reply, the Lord Advocate said that where poisonous substances were dealt with in the way of being dispensed, it was quite right that should only be allowed to be done by qualified persons. But in his view, where they did not need to be dispensed and were supplied by the manufacturer in the final form in which they were to be applied, he did not see that a trade or profession should have a monopoly of selling them, provided proper regulations were made and precautions taken that they would not be supplied or used for any other purpose than those for which they were meant.—("Gardeners' Chronicle.")

Liverpool Horticultural Association.—The annual dinner and social evening in connection with the above Association has become quite an institution, and from a social, as well as a gardening point of view, was again highly successful. A few old faces were absent, but younger members were there to fill their places, and to get a glimpse of friends meeting, as gardeners can when on pleasure bent. W. Fletcher Rogers, Esq., was Chairman, and right well he acquitted himself. Mr. T. Foster, Chairman of the Association, looked beaming, as, indeed, he well might at being able to bring together a force of 130. Mr. Mercer was here, there, and everywhere; Mr. Blackmore busied himself with subscriptions, and Mr. Harold Sadler, the courteous Secretary, gave everyone a kindly greeting. The loyal toasts were never more heartily proposed and responded to, and the collection for "The Absent Minded Beggars' wives and children, notwithstanding the many other funds for the same purpose at present in the city, realised £3 3s. 3d. The musical programme was of the usual excellence, and the conviviality of all present was greatly enhanced by the gift of cigars by Messrs. R. P. Ker & Sons, who were represented by Messrs. R. P. Ker, A. W. Ker, B. W. Ker, F. Ker, and Mr. Ranger. Messrs. Rowlands were also present, as were Messrs. Wilson (T. Davies & Co., Wavertree), Finnigan (Mr. H. Middlehurst's), Smith, of Birkenhead, and others. The votes of thanks to Chairman and artistes closed a most pleasant evening.—R. P. R.

Death of Mr. John Nunns.—We regret to announce the death of Mr. John Nunns, who passed away at Wimbledon on the 15th inst. at the age of seventy-one. He had retired from the profession for some years, but was for twenty-six years head gardener to Sir J. D. Llewellyn, Bart., at Penllergare, near Swansea.

Watering in Winter.—In the *Journal of Horticulture* of January the 4th I read the notes by "J." on Winter Watering of Plants. I would make particular reference to watering plants more or less dry on the surface. My present charge consists of a number of houses of plants to water every morning, and I start work each morning at seven o'clock when it is not too clear to see if a plant is dry or damp by looking at the surface. A sure way of knowing what plants require is sharply rapping each pot with the knuckles, as a clear ringing sound invariably indicates a want of water. I have frequently found plants damp on the surface and yet dry at the centre. There are many plants that only require just sufficient to keep them alive in winter. Watering is an art which should be thoroughly studied, as it has a very material effect on success in plant growing.—BALLYDRAIN.

Select Cactus Dahlias.—At the recent annual meeting of the National Dahlia Society the members selected the following as amongst the best Cactus Dahlias:—Alfred Vasey, Arachne, Beatrice, Bridesmaid, Britannia, Capstan, Casilda, Charles Woodbridge, Cinderella, Countess of Gosford, Countess of Lonsdale, Cycle, Ebony, Ethel, E. J. Deal, Falka, Fantasy, Fusilier, Green's White, Harmony, Harry Stredwick, Innovation, Island Queen, J. F. Hudson, Keynes' White, Lady Penzance, Laverstock Beauty, Lincius, Madame M. Henson, Magnificent, Major Weston, Mary Service. Mr. E. Welsh, Mrs. Barnes Mrs. Carter Page, Mrs. John Goddard, Mrs. Leopold, Mrs. Saunders Seymour, Mrs. Wilson Noble, Night, Ranji, Regulus, Starfish, Stella, The Clown, Tillie, Uncle Tom, Viscountess Sherbrooke, W. Treseder, and Zephyr. The sixteen varieties certificated by the Society in 1899 are recommended as deserving a place among the best, and will be included in the Society's list.

The Weather in 1899 at Belvoir Castle, Grantham.—The prevailing direction of the wind was west on 107 days. The total rainfall was 22.64 inches; this fell on 172 days, and is 4.22 inches below the average for a year. The greatest daily fall was 0.98 inch on October 1st. March and August were the driest months, May and October the wettest. Barometer (corrected and reduced): highest reading 30.761 inches on January 26th at 9 A.M.; lowest reading 28.355 inches on December 29th at 9 P.M. Thermometers: highest in the shade (Stevenson screen) 87° on August 25th; lowest 11° December 14th. Mean of daily maxima 56.16°; mean of daily minima 40.62°. Mean temperature of the year 48.39°. Lowest on the grass 8° on December 14th; highest in the sun 139° on July 19th. Mean temperature of the earth at 3 feet below the surface 49.49°. Total sunshine 1752 hours 30 minutes. There were fifty-six sunless days. The total sunshine is the most recorded since the instrument was erected in 1894. The mean temperature of the year is the same as it was in 1897.—W. H. DIVERS.

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet.

On the whole the weather has been dull with brief intervals of bright sunshine. Rain fell on five days. There was a dense smoky fog on the evening of the 20th inst.

BRACEBRIDGE MANSE.

SOME weeks ago when penning a few notes relative to Doddington Hall, for the pages of the *Journal of Horticulture*, a promise was made that some reference to the Rev C. C. Ellison's gardens at The Manse, Bracebridge, should be given, and that promise is about to be fulfilled. It is no light task to undertake, for the garden is by no means orthodox either in its style of formation or in its present-day maintenance. On every hand, though the space is comparatively limited, there are evidences of an original mind whose conceptions are unique, and are carried out with a boldness that is strikingly characteristic of the source from whence it sprung. A generation ago there was a flat meadow; now there is a garden of which it would be an impossibility to find an exact counterpart within the confines of the British Isles. It is like nothing but itself, and is testimony to the energy of its owner and originator, the Rev. C. C. Ellison.

It was between thirty and forty years ago that the task was commenced to turn the flat field into an interesting garden, for it was about that period when its owner was severely bitten with a desire to "garden." And he has been gardening ever since. True, there have been days, perhaps months, when a slackening has come, but it has only proved a time of rest which brought in its wake renewed vigour and activity with fresh ideas and improved principles. There has always been even in those days of repose a deep-seated love for gardens and gardening, and if Mr. Ellison could be induced to tell in writing of the joys and sorrows that beset the path of the enthusiastic amateur they would bring pleasure to every reader of our Journal. He is a scholar, a brilliant *raconteur*, and one who has a happy knack of conveying information in the best possible style—that which interests and amuses as well as instructs.

The Manse garden is practically divided into two distinct sections, one for fruits and the other for Roses, and it would be difficult to say which portion is the better. I need not attempt to decide, but can safely leave the one in the hands of fruit men, and the other to the partisans of the queen of flowers. Then, too, there are borders of old-world flowers, as well as a pond in which some of the choicer Water Lilies have got to thrive. This is surrounded by flowering and foliage trees, and, small though it is, it presents more than one view which could not fail to charm the lover of Nature's beauty. Here we have the serpentine walk, while anon we enter the Palace of Truth, and later pass through St. George's Channel; not the one that cuts England's shores from those of Ireland, but a creation of Mr. Ellison's that affords a pleasant shade on the hottest of summer days.

The serpentine or snake walk is admirably named, for it takes the traveller by devious ways through the Rose garden to the fruit quarters. Not only does it wind "in and out and round about," but goes up and down dales on which lives a family of Roses comprising some 3000 members. The plants have not all the same aspects, but are placed where it is found they flourish best. Some varieties are represented by considerable colonies, and others by lesser numbers, but almost the whole of them are healthy and clean, while several make really luxuriant growth. None can imagine the beauty of one of the Rose gardens, and those who have seen it in its most attractive

garb do not care to set themselves down to work out such a task as an accurate description. Standing at one point in the snake walk the ground clothed in Roses falls gently beneath one's feet and rises and falls to the centre, whence a bolder ascent commences and carries the eye to a grand Yew hedge and to trees above with the country beyond; it is an ideal position for this most popular of flowers.

The rosarians may here cry out for names of varieties, but at this the line must be drawn, or the available space would be swallowed ere the fruit was reached. Suffice it to say that numberless varieties have been tried, and those that succeeded best are retained, but the failures—well they find a resting place in a less congenial spot. In only one respect, so far as I observed, is Mr. Ellison what might be termed a severe man. This is when he discovers a speck of mildew

or a lone and solitary green fly on his Roses. Then severity is scarcely the word; it should be death, for the enemy is attacked with such determination that even Mr. Raillem's advice given in these pages, when speaking of flowers of sulphur for mildew, to "rub it in" is none too strong. The sulphur steps in and the mildew rushes out. Green flies may not be dealt with in precisely the same way, but an equally efficacious course is adopted. Mr. Ellison evidently believes in getting home a heavy blow at the outset of the battle.

As we continue our march of progress we reach the aforesaid Palace of Truth, which is in reality a charmingly embowered seat, where occasional meetings of gardening enthusiasts take place. Needless to say with such a conclave conversation waxes warm, and, as our guide put it, stories are told. The seat and surroundings could many a tale unfold were they endowed with speech, and the horticultural world would be the wiser for the knowledge. Striking hence by another path we traverse St. George's Channel, which is so named from the fact that on one side are English while on the other are Irish Yews. Stormy passages through the *real* channel are of comparatively frequent occurrence, but we can answer for our journey by Mr. Ellison's route being essentially pleasant and peaceful. But we must press on or we shall fail to reach the all-important fruit trees, of which their owner is justifiably proud.

The quarters containing the fruit are of some considerable extent, and include amongst the 1500 or so of trees babies only just planted to middle-aged

specimens of thirty years or rather more. The juveniles are certainly pictures of health and sturdy vigour, as are many of the older trees. Some, however, are by no means attractive, as they illustrate to demonstration the effects of canker, and it is of those that Mr. Ellison is most proud. It may be taken as probable that the fact of almost all his trees being attacked by this insidious enemy was the cause of our host's first lapse into inactivity or lethargy. He feared that all hope of success was gone, and was consequently in despair. Some good friend, however, advised an attack on the canker, and the very idea was sufficient to stir the latent energy into life. The result of this was that the saw and knife came to the fore, as well as boiled oil and Stockholm tar, which, in addition to attention to the roots, very quickly made their presence felt for the better. The wounds after cutting and dressing grew over, and the trees took on a renewed lease of life.

Tree after tree was examined, and though remains of canker could be seen, the active disease was a thing of the past. If it recur on

FIG. 15.—APPLE COX'S ORANGE PIPPIN AT BRACEBRIDGE.

any tree the remedies are applied with care and promptitude, and with invariable good results. Hence it is that scores of Apple trees, which were condemned to death by fire, are now thriving, and producing regular crops of sound fruits. Let those persons, however, who would

be desired than are there to be seen for the asking. The collection, particularly of Apples, is most excellent, and many are the grand specimens of individual varieties that are produced. Glance at the photographic illustration (fig. 15) and a glimpse of a couple of branches

FIG. 16.—ABUTILONS.

emulate Mr. Ellison remember that the roots receive consideration in a rational way as well as the branches. We might advise these who are not believers in pinching to steer clear of *Bracebridge Mansie*, or they will have the wind completely taken out of their sails inside fifteen minutes. Certainly no better examples of its advantages could

of Cox's Orange Pippin will be seen that may be taken as typical of scores of other trees in the garden.

Though the trees are mainly of bush form, there are representatives of other shapes, as well as some beautiful examples of training on

the walls. The trees are young, it is true, but we hope that as they attain to years of maturity they will prove to "A. N. O." that the art of fruit tree training has not quite passed to an untimely grave. We had a peep into the fruit room, and found it splendidly stocked with handsome produce, most of which will probably ere now have gone the way of all good fruit. Besides the Apples, Pears, Plums, and Damsons there are the small fruits; but we must pass these over with the simple assurance that they are well worthy to rank with their larger *confrères*, to which more specific attention has been given in these notes.

Many persons will think that no ordinary man could have much spare time when such attention is devoted to the garden, particularly when it is remembered that there are other duties which are even more important. Not only, however, do these matters have attention, but Mr. Ellison has another hobby—namely, carving. This is done with lathes that are quite perfect, and the ivory that has been worked proves the evidence of a master hand; indeed, Mr. Ellison is acknowledged as one of the foremost carvers in England, whose work is much sought at exhibitions of this nature. Unfortunately it is beyond our scope to describe either the man, the carving work, or the machines, so we must leave Mr. Ellison to his hobbies, while expressing gratification at the visit that was paid at the close of last summer. —H. J. WRIGHT.

FLOWERING PLANTS FROM SEED.

ABUTILONS.

A GOOD strain of Abutilon seed will produce plants that will give flowers in the several colours of crimson, yellow, red, and white. The drooping, bell-shaped blooms (fig. 16, p. 75) are attractive on the plants, and can be used for cutting, as the flower stems are usually of a sufficient length for utilisation in glasses. Seeds may be sown in February in brisk heat. When the seedlings are large enough pot them singly in a compost of loam, peat, and sand, growing them in a moist atmosphere until they attain a fair size. It is desirable to top the shoots a few times so as to make the plants bushy, which improves their appearance and renders them more floriferous. As the plants become well established give them greenhouse treatment in an airy, sunny position, always affording water before the plants suffer, as they are rather impatient of moisture. If the plants grow too tall they may be reduced by cutting down in spring. When the shoots break into growth repot the plants. Varieties it is desirable to retain may be propagated from cuttings which root in a compost of light rich soil in a moist temperature of 65° in spring. One of the best old named varieties is *Boule de Nègre*, and this is chiefly perpetuated by cuttings. The flowers are white with yellow stamens.

ANTIRRHINUMS.

Antirrhinums, commonly known as Snapdragons, are hardy perennials which can easily be raised from seeds in heat and flowered the ensuing summer. Formerly seeds were sown in autumn, or cuttings inserted, but this requires frame space in winter which can be better utilised. For producing very charming beds, either in separate or mixed colours, the Tom Thumb varieties are excellent. Some object to them because of their pigmy, dwarf, or formal character when in bloom, but they are nevertheless attractive, especially a mixed bed of various colours. The tall varieties are the best for borders, because the spikes are longer and more useful for cutting. In addition to these there are now intermediate varieties which are as beautiful as the others. Seeds may be sown in pans at the present time, and encouraged to germinate in heat. In a week or two after place them in a cooler place, eventually pricking out the small plants in boxes, from which they may be transferred to the beds or borders in May, 4 to 6 inches apart.

FIBROUS-ROOTED BEGONIAS.

These Begonias, when raised from seed early in the year, can be flowered outdoors in beds the same season. A bottom heat of 65° to 70° must be at command, and the seeds should be sown in pans filled with a mixture of loam, peat, leaf soil, and sand. Drain the pans thoroughly, and make the compost fine and level on the surface, giving a gentle watering. When drained sow the seeds thinly, and dredge over a very slight covering of white sand. Place on the pan a square of glass to prevent the moisture evaporating from the soil. On this lay paper to shade the seeds from light. No water ought to be necessary before the seed germinates, and when it is required it should not be given at the top, but stand the pot in water until moisture begins to percolate through the surface. It is best to remove the pan from the water as soon as the first drops of moisture are seen on the surface. The seedlings ought as soon as practicable to be transferred to fresh soil in well-drained boxes, still keeping them in heat and moisture. Lift them carefully from the seed pan with a flat notched stick, and place 2 inches apart in the boxes filled with similar compost to that employed for sowing the seed. When the plants are well established in the boxes and growing vigorously, they may be introduced to a cooler temperature, where they will gradually become inured to harder treatment for final planting out in June.—E. D. S.

ROSES UNDER GLASS.

THE month of January is a busy time with those who grow Roses under glass extensively, as the plants need pruning and the borders dressing. Those planted out are not generally forced very hard, as so much better results are obtained by letting them advance steadily to give blooms during April and May. The early supply of flowers being obtained from plants in pots, a good stock of these should be pruned at once and placed in a light structure where the temperature ranges between 55° and 65°. A vinery just started is an excellent place for them, as the moist atmosphere and gradually increasing temperature suit both Vines and Roses.

In pruning the Hybrid Perpetuals I like to cut them back to one or two eyes, leaving a few strong shoots longer at points where they are required to fill gaps. Notwithstanding much that has been written to the contrary, nearly everyone prefers a Rose of good size and pure or brilliant colour to a smaller bloom of any given variety, and to secure fine blooms hard pruning must be practised with nearly all varieties of H.P.'s. In regard to dwarf Teas less severe pruning may with advantage be practised, but I am no believer in the let-alone practice which some growers adopt. When this is followed the bushes become crowded with weak growths that give only flowers of moderate size, and the few really good blooms which are produced are borne on strong shoots which break from the old wood or are thrown up from the stools. With such varieties as *The Bride*, *Catherine Mermet*, *Ernest Metz*, *Grace Darling*, and *Madame Lambard* I cut away all weak growths, shorten strong shoots to three or four eyes, and moderately strong ones to one or two. When this practice is followed nearly every bud which bursts brings a splendid flower, and from a commercial point of view one good bloom is worth two or three smaller ones.

After pruning a little of the surface soil should be removed, a dressing of some good chemical fertiliser given, this to be covered with a layer of sound loam enriched with fresh horse manure or dried cow manure. But I pin my faith principally on chemical manures for Roses in pots, as nothing seems to bring out such vivid colour in the blooms. In pruning climbing Roses which are planted in borders and trained to the roof of a house or other trellis, evidently different treatment is necessary, as such plants grow very strongly and flower splendidly on long shoots which are thoroughly ripened. Take for instance *Maréchal Niel*, at this season little if any pruning is needed; that operation should have been performed shortly after the blooms were cut last season. If the worn-out shoots were then cut away, to make room for the strong growths just starting, the trellis should now be covered with hard firm shoots, ripe almost to the points, and only the unripened parts need cutting away now. This fine Rose often produces a number of short, wiry looking shoots near spurs, or from the old wood, and such I find generally bear blooms of good size and fine colour. Climbing *Niphetos* and climbing *Devoniensis* are both very strong growers, and if the shoots are freely thinned during summer such growths ought to be thoroughly hard and ripe throughout the greater part of their length, and only need shortening back to hard wood.

But on the other hand, it is quite useless to have long green-looking shoots, as they only produce weak growths instead of flowers. The plan to follow therefore is—leave as much ripe wood as can be kept without undue crowding; cut away the remainder. When a large amount of space is covered by old trees, they succeed well by spurring the shoots in closely, and cutting some of the worn-out ones away each year, to be replaced by strong breaks.

Cheshunt Hybrid and *Reine Marie Henriette* flower splendidly on long, strong shoots, provided they are hard and ripe. Training thinly during the summer is, of course, the way to secure such growths. Unripened points must be cut away, and weak shoots pruned in closely. Young plants of *W. Allen Richardson* flower well on long shoots of the previous year's growth, and after flowering numbers of moderately strong growths break from them. These flower at the points later in the season, and from almost every joint the following year. After that I like to remove a few of such two-year-old branches annually to make room for young ones. Two old favourites, *Belle Lyonnaise* and *Gloire de Dijon*, flower well either when treated on the long shoot or spur system of pruning, but when grown as climbers I prefer the former method, as the space can be kept evenly furnished with shoots of almost equal vigour. Other varieties have their special characteristics, and need treating according to the lessons taught by close observation; indeed pruning of all descriptions.

cannot be successfully performed under various conditions, except by those who study the matter and act upon the experience thus gained.

After pruning Roses which are planted out the border should receive some attention, and if roots are plentiful—as they ought to be—remove a little of the surface soil, dress with chemical manure, then add a thin layer of loam and a coating of manure, if the position is one in which the latter will not be objectionable in appearance; should it be so place the manure on first and cover with soil.

Trees which are not thriving satisfactorily ought to have some of the soil removed, and good loam with a third of manure and a little soot added, substituted for the old soil. As long as one finds the borders packed with roots, an annual top-dressing and liberal feeding will secure good results; but whenever roots are scarce and the soil sour, the golden rule to observe is—remove and replace it by sound sweet compost. After the borders have been thus dealt with, and the soil has been found fairly dry, water thoroughly with tepid water, but when the soil is wet, or roots not plentiful, defer watering for a time. —ROSARIAN.

COMMERCIAL GARDENING,—No. 2.

A CATCH CROP—FRENCH BEANS.

IN the early spring days Cucumber growing is found very expensive, on account of the large quantity of fuel burnt to keep up sufficient heat. When, a few years ago, the price of early Cucumbers fell from 12s. to 6s. a dozen, growers had to look round and see what they could grow in the houses to help to pay for the fuel. The catch crop grown in the small (12 feet) Cucumber houses must be one that will not take up much room, and will come to maturity early; and nothing has been found more suitable for this purpose than French Beans.

WHEN TO SOW.

The Bean seed should be sown a fortnight after the Cucumber seed, in shallow boxes, those used for Tomato seeds and Chrysanthemum cuttings being the kind frequently employed. In case any readers do not know the sort referred to, it may be said they are about 7 inches wide, 12 inches in length, and 1½ inch deep. These boxes each hold forty beans. The soil used for sowing is any ordinary soil, that in which Chrysanthemums have been growing being very suitable. Be careful, however, not to use any that may contain any pest or disease harmful to Cucumbers, for although our friend Mr. "A. D." may make light of our old enemy the eelworm, he would find it no easy matter to deal with if he were a market grower.

When the seeds are sown place the boxes in the house in which the Cucumbers are being raised. The seeds will, if given plenty of water, germinate very rapidly, and the boxes should be removed to a cooler situation as soon as the plants appear. The successful Bean grower always has dwarf sturdy young plants, and plants them out as soon as the first two leaves are half developed. The secret of a good crop of Beans is the planting out just at the time named.

PREPARING FOR PLANTING.

The Cucumber houses should be whitewashed and painted, and the soil put into heaps ready for the "Cue" plants. Most Cucumber houses have two flow pipes and two returns in each house. The former run along the back, and the latter are put more or less down the middle of the house, generally from 3 to 4 feet from the flow pipes. The Beans are planted in rows, one on each side of the return pipes. By this means we get four rows of Beans in each house.

Knowing now where the Beans are to be planted, a layer of manure should be spread along where the rows will come, and if a little basic slag and kainit is spread on the manure, the Beans and "Cues" will be all the better for it, and will repay the grower for his thoughtfulness. We generally spread about 3 lbs. of the former and 2 lbs. of the latter to every 100 feet of row. Dig in the manure, taking care to mix it well with the soil.

PLANTING.

The Beans should be ready to plant at the same time as the Cucumbers. Stretch a line along a foot or 15 inches from the pipes, and dib in the Beans 4 inches apart. Give them a good watering as soon as the planting is finished, and then only water when necessary. When the Beans are 6 inches in height put a few small stakes on each side, and a row of string to keep the plants from falling about.

As soon as they commence flowering give them a little weak stimulant in the form of liquid manure. The latter is not always available, but what is even better than this is a mixture of one part of nitrate of soda and two parts of superphosphate, 1 oz. in a gallon of water. Give alternate waterings, first with clear water and then with the liquid manure.

It is hoped none of your readers will be surprised at this recommendation of nitrate of soda for a leguminous plant. Writers of horticultural science may tell us that this class of plant can obtain its nitrogen from the atmosphere. The fact is not disputed, but we

cannot wait while the moving air brings sufficient of this food to our plants, so we give them nitrate at the root, and find it pays.

PICKING AND PACKING.

About a month from the time of planting the Beans will be ready for picking. Do not pick them too soon; but on the other hand, do not keep them too long. A little judgment is necessary. Some growers pack the Beans in boxes, which will hold about 6 lbs. each, but the majority put them in overhandle baskets. Line the baskets with paper, and as the Beans are picked lay them in neatly and evenly, cover with paper, and tie them down with plenty of raffia.

VARIETIES.

We have never grown more than the two following varieties of Dwarf Kidney Beans—viz., Ne Plus Ultra and Osborne's Forcing. There is not much to choose between these two, but if we had a casting vote we should give it in favour of the last named.

RETURN FOR OUTLAY.

Beans in the spring sell readily. In a mild winter they may not fetch more than 10d. per pound wholesale, but when other vegetables are scarce they will often sell from 1s. 6d. to 2s. 6d. per pound. We have managed to get from houses 100 feet long 100 lbs. of Beans, and our average price was 1s. per pound.—TOM SLOWMAN.

FRUIT TREE TRAINING.

It is evident that in some establishments the art of tree training is not strongly in evidence. It is very pleasing to see the whole space on walls closely covered with well-trained fruit trees laden with luscious fruit. Very often large empty spaces are noticeable, and trees may be seen cut so clumsily that large decaying snags are much in evidence; these eat into the permanent branches, and in due time are the forerunners of canker and death. Pruning should be done on every species of tree or shrub in a manner so that there is nothing left to do mischief. There should be no long sloping cuts, but manipulated with a twist close to the bud, which leaves nothing to die back, so that in the course of time (a season or two at most) the wounds are healed, and the bark has concealed the cut.

Such was the practice of the late Mr. Pitman, foreman in the grounds of the late Messrs. Osborn & Sons at Fulham Nurseries. Many practitioners of the art of tree raising at the present time claim to have been under Pitman, and received tuition from him. They may have been; but in some cases I have seen of late years the pupils had not been very apt disciples, as the trees passed through their hands are as unlike Pitman's as a Clydesdale horse is to a well cared for thoroughbred.

A mistake is very general, and that is the young growths are not trained into form as soon as they are made, but left to grow as they may; then such cannot be formed into handsome shoots. A well-managed shoot should be as clean and straight from the stem as a gun barrel. Such was Mr. Pitman's practice. I watched his work carefully while I was under him for nine months. I never see any trees like them now. If trees are not well started at first, they are always faulty afterwards.—M. TEMPLE, *Carron, N.B.*

STEM ROT OF CARNATIONS.

MESSRS. CHARD & ADAMS of the Rhode Island Experiment Station have been making quite extensive experiments in this little understood disease, which at the present time has perhaps more terrors for the American Carnation grower than any of the other numerous ills to which the plant is subject. The experiments were designed to show the influence of clean sand *versus* old sand for propagating vigorous as against diseased cuttings, and manure *versus* chemical fertilisers as influencing the prevalence of disease. Tests were also made of the use of Bordeaux mixture. The experiments were begun in the spring of 1899, some 1500 cuttings of the variety Flora Hill being used. A part of these were obtained from plants among which stem rot had been very prevalent, while the others were from healthy stock.

Although the experiments have not, says "Gardening" (America), progressed far enough to be regarded as conclusive, certain indications are pointed out as well worthy of note. The most marked is the great importance of using fresh sand for propagating, some of those propagated in old sand showing losses of over one-half from stem rot. It is unsafe to dip the cuttings in Bordeaux mixture, and no special benefits seem to result from it. The experiments do not show any increase of the disease in soil fertilised with stable manure.

One of the fungi causing the disease is thought to be the same as that causing the rot of sugar Beets and the damping-off in other plants. It would seem safer, therefore, to avoid soil in which Beets have been grown, and not to use sand in which cuttings of any kind have been rooted—that is, use a new clean sand for each stock of cuttings. The conclusions in regard to propagating sand are in accord with the practice of many of our best commercial growers, and should be heeded by all. It is to be hoped that these gentlemen may be able to continue and complete their experiments.

MRS. G. CARPENTER.

THIS is a valuable Chrysanthemum to grow for the supply of late pink blooms, a colour that is very scarce. The variety does not lend itself to a mass of bloom, as many of the side buds will not open; but a plant in a 9-inch pot will perfect a dozen or more charming flowers about 4 inches across as late as Christmas.—H.

CLINTON CHALFONT.

ON page 26 Mr. Molyneux mentions a white sport from this fine decorative variety. Many catalogues also quote white Clinton Chalfont. It does not seem to be known that Clinton Chalfont is a yellow sport from a white variety, J. H. White, and the apparent sport from the yellow is simply a reversion to the parent.—W. J. GODFREY.

YELLOW ETOILE DE LYON.

I HAVE before me a pure yellow sport of this one time favourite which gives promise of being valuable for late flowering. Like all other sports, the newcomer has the parental characteristics. Whether it will be as much sought after by exhibitors as its parent, time only will prove, but if it is cultivated only for the production of late flowers in quantity it will serve a useful purpose.—E. M.

J. CHAMBERLAIN.

THOSE who have not tried this crimson variety for late flowering should do so. The blooms hold their rich tint remarkably well quite up to Christmas, and the habit of the plant lends itself to a bushy specimen. We were more than pleased with it compared with the other best crimson sorts. It is a trifle small for exhibition purposes. This has caused many to regard the variety with less favour than it deserves for general culture.—S.

CRIMSON CARNOT.

CERTAINLY the note on page 6 of the Journal was enough to whet the appetite of all Chrysanthemum lovers. Yet after reading it one feels a bit sceptical. A crimson Carnot must be obtained as a sport to be the same as the parent, except colour, and we have not up to now heard of a crimson colour coming from either a white or a yellow.

A form resembling the charming type named may of course be raised from seed, but to call the same Crimson Carnot would be misleading. A variety already exists—Hon. W. F. D. Smith—which has been described by the high-sounding title that heads this note, but who that has grown it does not think the same a bit overdone? Another misleading instance is the variety named Red L. Canning. This was obtained from seed; not as a sport from the type. It somewhat resembles L. Canning, in being a dwarf grower, and is fairly late, but it should not have been awarded a first-class certificate because of that, as Red L. Canning. The new one at once gained a notoriety its merits did not deserve.—SCEPTIC.

SHOW SCHEDULES.

MR. E. MOLYNEUX takes exception (p. 26) to my advocacy of standard and pyramidal-trained Chrysanthemum plants. I am, however, not by any means alone in the opinion that their inclusion would relieve the monotony presented by an assemblage of the usual bush-trained plants, which require a host of inartistic stakes to bring them into shape. From an exhibitor's point of view no doubt the latter system is favoured, owing to the greater facility it has in affording a wide area for a more direct face of the blooms when staged, and also less trouble incurred in training the specimens into shape than that entailed by the systems advocated. Furthermore, I fail to see any more objection to Chrysanthemum plants grown as indicated than the almost mathematically trained specimen plants, such as Indian Azaleas, Ericas, Ixoras, Stephanotis, Allamandas, Apelexis, and a host of others, which form so great a feature at the principal flower shows.

Respecting "miscellaneous groups arranged for effect," I am fully cognisant that, in a general way, schedules allow the proviso that "ornamental foliage" and other plants may be introduced into Chrysanthemum groups, but what I intended to convey was the desirability of offering prizes for groups of plants, exclusive of Chrysanthemum or otherwise, according to the means or taste of the exhibitor.—W. G.

[Our contributor is still under a misapprehension. We may repeat that prizes are frequently offered for groups of miscellaneous flowering and foliage plants at Chrysanthemum shows from which the autumn queen is rigidly excluded.]

KINGSTON CHRYSANTHEMUM SOCIETY.

AT a recent fortnightly meeting of the Kingston Hill Gardeners' Improvement Society, Mr. Alexander Dean delivered an excellent paper on flower shows, which was listened to with interest by his audience. Mr. Dean afterwards introduced the subject of the Kingston Chrysanthemum Society—viz., was it desirable to continue that Society or substitute a summer exhibition in its place?

This produced an animated discussion from one or two of the Committee of this Society (who had been invited to attend the lecture), and also from several of the members of the Gardeners' Society, who have not as yet given any support to their Chrysanthemum loving brethren. The chief grievance seemed to be that the collector had not called on them all for subscriptions, which I hope will be remedied when another season comes round. A simple remedy for this evil would have been to have sent or taken their subscription.

A proposition to limit the exhibition to the boundaries of the Kingston poor law union found a good deal of favour amongst those present. In support of this it was urged that the large amount of money spent in the principal open classes in past years brought no appreciative return, either in competition or subscriptions. This, without doubt, is perfectly true, owing perhaps to the numerous shows now held on nearly the same dates, and also the fact that large growers usually take their best flowers where the prizes are most attractive.

One speaker in suggesting improvements in the Kingston schedule went in strongly for introducing classes for Chrysanthemums staged in vases, similar to those seen at the Aquarium and elsewhere. I should certainly agree with him, to include a class or two staged in vases, especially so in the amateur and cottagers' sections, which are too often neglected, in suitable classes for the display of their flowers.

It is questionable, however, if large classes for Japanese, at local exhibitions, draw the amount of competition that is expected of them. At Wimbledon, for instance, the chief class which was staged in vases drew one competitor; whilst at Putney a similar class brought two exhibitors. Single vases at Wimbledon, however, made a splendid show, nearly a dozen competing in one particular class, which clearly shows that whilst many can stage a few blooms it is only a limited number who show in the larger classes.

A great point in favour of long-stemmed flowers is their usefulness for home decoration after the show; whereas their shorter-legged brethren of the board are practically valueless, more especially the front row flowers. Classes for Violets were also mentioned, but these it appears have already been tried at Kingston without much success. A plant that has received much attention in the locality might well be honoured with recognition in the schedule—viz., the pink Begonia Gloire de Lorraine. A class for twelve or nine pots would make a striking and effective display, and, judging by its popularity in the district, a strong competition would be forthcoming.

The difficulty of securing a suitable building is also a vexed question, the Drill Hall being a large structure, although perhaps in past years it was small enough. The situation of the hall is also not exactly central, but, as Mr. Dean remarked, this probably does not affect the attendance to any extent. The re-introduction of Chrysanthemum groups would also tend to brighten and fill the sides of the hall, making separate and smaller groups for single-handed gardeners, who are another division of gardeners that too few classes are usually provided for, according to their means and advantages.

The Society, as it stands now (we were informed by the Chairman) is clear of debt, therefore any idea of its ceasing to exist should not be entertained, as, with a good working Committee and an energetic Secretary, surely the Kingston Show could be once more put on a firm basis.

Towards the close of the meeting Mr. A. Dean was proposed as successor to Mr. Elsam (who has lately resigned the secretaryship), but Mr. Dean firmly declined the honour, his time being fully occupied with other work. Perhaps a more fitting occasion to nominate a Secretary would be at the annual general meeting of the members of the Kingston and Surbiton Chrysanthemum Society.—EXHIBITOR.

AQUILEGIA PYRENAICA. — An excellent article on page 32 gave a very interesting account of the larger number of the Aquilegias or Columbines. One charming species not mentioned in that article, and which is particularly suitable for small rock gardens, is *A. pyrenaica*, a small and graceful-looking Columbine from the Pyrenees. It seldom attains to a height of more than a foot, and is commonly seen dwarfer. It has finely cut leaves, and handsome deep blue flowers, which open from May to June. It grows well in sandy peat; but, although it likes ample drainage, does not do well in a very dry soil. Some plants I have on a rather dry rockery have bloomed and grown in a less satisfactory way than those on another which had moister soil. This Pyrenean Columbine is not a new occupant of our gardens, as it was introduced in the year 1818. It may be increased by division, but it is also easily raised from seeds.—S. A.

APPLE STANWAY SEEDLING.

THE new Apples that were shown before the Fruit and Vegetable Committee of the Royal Horticultural Society during 1899, and which were recommended for the award of merit, were exceptionally numerous. At several successive meetings varieties were honoured in the direction indicated, and one—Chas. Ross—was considered so meritorious as to be deserving of a first-class certificate. The last variety to receive an award of merit was Stanway Seedling (fig. 17), which was exhibited on December 19th, 1899, by Mr. T. Kettle of Colchester. As our illustration clearly shows, this Apple, which is decidedly over medium size, is of handsome conical form, tapering towards the apex, and of uniform clear yellow colour except in the cavity of the stalk which is bright green. The eye is small and closed, and is set on one side of the axis. The tube is conical, and the stamens median. The stalk is very short and deeply inserted in a cavity which has a small, fleshy protuberance on one side. Stanway Seedling is a culinary Apple of much promise for use at Christmas.

HORTICULTURAL EXAMINATIONS.

IN considering the examinations in their more general application, it may not be possible to formulate an opinion so readily as in the two cases to which reference has been made, but I fear there will be some difficulty in arriving at a conclusion other than to the effect that the results have fallen short of expectations. If they are intended to show that the holder of a certificate is well qualified to undertake the responsibility of a garden they have unquestionably failed. For this purpose the certificate of the first-class is of little service to the holder. The certificate shows, of course, that the holder had a sufficient acquaintance with theoretical matters to pass the examination to the satisfaction of the examiners; but to a man who has obtained a position in the garden, a distinction which can be obtained by a youth or a girl in her teens can be of little if any use to him. If it be said that the examinations are only intended for testing the knowledge of many people, let it be so stated, and the examinations be described as elementary. The questions are by no means of an elementary character, and it passes my comprehension how a youth of sixteen or seventeen, or a miss in her teens, should obtain nearly full marks in dealing with such a paper as that set at the last examination. Sixteen questions were given, and of these one half had to be answered in two and a half hours. I have selected eight as fairly representative of the paper, and these are as follows:—

What differences exist between the manner and places where rootlets arise from roots, and branches from stems? Of what use are branches, and what trees have none?

Give any instances of failures, and state your opinion as to their causes, in crossing distinct species. What are the general characteristics of hybrids?

Describe the flower of the Pea, of a Primrose, of a Salvia, and of any Orchid, and explain how they are adapted to insect pollination.

What are the injurious effects of (1) too much water; of (2) too great a heat; and of (3) excessive drought, upon plants?

Is it possible to obtain a supply of Roses all the year round from an English garden? Describe their propagation and culture under glass and in the open ground.

What are the most useful fruit trees* to grow under glass? Describe the best form of glass structure for the purpose, and the method of culture.

How would you proceed to obtain a succession of garden Peas and Dwarf Kidney Beans? Can they be obtained all the year round? If so, how?

What is the best aspect for a flower garden? How would you proceed to lay it out and stock it?

To answer these eight questions fully and accurately in the time allotted in a manner to justify the examiners regarding a considerable number of the papers as closely approaching perfection indicates a degree of ability on the part of the candidates that is at least surprising. I know something from practical experience of University and other examinations, and as I run my eye down the paper of questions and then turn to the class list I cannot restrain a feeling that there has been decided liberality in assigning the marks.

The class lists show, as might, of course, have been expected, that those who had the assistance of experienced teachers have been the most successful. In other words, the students attending the various colleges and schools in which horticulture is taught greatly predominate in the first class. I refer to this point for the purpose of stating that in the preparation of candidates the experienced teacher will constantly keep in view those points which are likely to tell in dealing with a paper of questions, rather than to concentrating his attention

upon grounding his students in the technicalities of the art. It is, I am prepared to admit, extremely difficult to avoid some amount of cramming in connection with horticultural as with other examinations, but it should, as far as possible, be discouraged. If we are to improve the educational status of gardeners we must teach them gardening rather than how to pass examinations in gardening, and unless we do that we had better return to the state of things that existed before the examinations were instituted.

Much might be accomplished in improving the existing state of things were we to more clearly understand the conditions under which gardeners are the most efficiently trained. I am not prepared to say that gardening cannot be efficiently taught in properly equipped schools, but I have no hesitation in stating that the best possible schools for the training of young gardeners are private gardens and nurseries. In these the young gardener not only obtains a training in the technicalities of the art, but is braced up, so to speak, by the influences that are brought to bear upon him, to engage with greater efficiency in the battle of life. I have for a long series of years constantly advised gardeners to take every possible advantage of their

FIG. 17.—APPLE STANWAY SEEDLING.

opportunities for the acquisition of a knowledge of principles as well as practice. I have, with equal persistency, advocated that this knowledge should be acquired in conjunction with practical work. In my opinion, therefore, the scheme under which examinations are held should be so framed as to encourage them to do this.

With a view to the attainment of this end I would suggest that the scheme should recognise three distinct grades of students, and include practical work in two of them. There should be the elementary examination, which might be conducted on much the same lines as now, without any restriction as to the eligibility of candidates. Then should follow the advanced examination in which practical work should have due prominence, and for this those only should be eligible who have had at least five years' experience in private, public, or market gardens, or nurseries, and have obtained a first-class certificate in the elementary examination. Following the advanced should be the honours examination, in which a candidate should, in addition to a paper examination, be required to show his proficiency in practical work, and also to show his ability in giving directions to the garden labourers for carrying out the details of garden work. Candidates for this examination should have had seven years' experience in gardens or nurseries or in both, and have obtained a first-class in the advanced stage.

A scheme such as I have thus briefly sketched would require careful preparation and involve some amount of difficulty in carrying it out, but the prospective difficulty does not appear to me to be sufficient to deter the responsible authorities from grappling with the question and endeavouring to formulate a scheme which will greatly improve the existing state of things and make the examination worthy of a country in which the practice of horticulture has attained to a higher degree of eminence than in any other part of the world.—(Conclusion of a paper read by Mr. GEO. GORDON, V.M.H., at a meeting of the Horticultural Club.)

* The word is intended to exclude Vines.

DEATH OF MR. JOHN FRASER, V.M.H.

MANY of our readers who have enjoyed the acquaintance of Mr. John Fraser will regret to learn of his death, which occurred on the 20th inst., at Woodford, Essex. Mr. Fraser was one of the best known of metropolitan nurserymen and valuers of nursery stock. He was a man of great ability and trusted integrity, while the genial nature of his disposition rendered him highly popular. In years gone by he was a famous plantsman, and one of the best exponents of the culture of hardwooded plants in the kingdom. Such specimens as he grew are now about extinct, and could only have been produced by more patience than appears to be general nowadays, and the greatest cultural skill.

For several years his chief nursery was on the borders of Epping Forest. For some time we believe it has been under the management of his son. It is famed for hardy trees and shrubs, and has been one of the chief sources of supply for several of the London parks. Of late years the deceased gentleman's services were in great demand as a valuer, for which his experience admirably fitted him, and his uprightness was proverbial.

He was also for a long time a leading spirit in many public functions connected with horticulture, and few men could speak more appropriately and effectively on the subjects that might be under consideration. Mr. Fraser has for years been a most useful man in the horticultural world. His unassuming manner and readiness to do what he could for any worthy object rendered him a general favourite, and his memory will be cherished by a large circle of friends. He was an old member of the Floral Committee, and by this body a vote of condolence was passed at the last meeting with the family on the loss of its estimable head. Mr. Fraser was seventy-eight years of age.

A SWEET PEA FESTIVAL.

FEW persons interested in gardening will venture to dispute the popularity of Sweet Peas, or to question their right to hold a position in the front rank of garden flowers. They have a beauty, a grace and a charm that are peculiarly their own, and when to those most desirable attributes is added a delicious fragrance we find a combination of virtues that is not to be commonly found amongst plants. Little wonder then that they have grown in general favour, and are yearly becoming more and more appreciated, especially for various decorative purposes to which they are so admirably adapted. Not only are Sweet Peas held in high esteem by professional gardeners but also by every amateur horticulturist in the country, while the rural cottage garden that has not its one or more rows is a striking exception to the general rule. The natural result of this extraordinary popularity has been that varieties have during the past two decades multiplied enormously, and unfortunately many of them show scarcely any perceptible difference from numbers of others. This is most regrettable and calls for reform.

To meet this evident want, and with a view to reducing order out of chaos, it has been decided to hold at the Crystal Palace this year an exhibition of Sweet Peas. The occasion of having so many varieties in the very best of condition exhibited at one and the same time will be seized to classify the varieties, for which purpose a representative committee of experts will be selected. These gentlemen will bring their knowledge to bear on the flowers, and the result of their efforts will most certainly be for the general good. But it has been decided to go further than this and to have a conference during the show, when papers will be read which will treat of the plant from various stand-points, and these alone will form a valuable addition to horticultural literature.

The reason this particular year was chosen lies in the fact that it is the bi-centenary of the introduction of the Sweet Pea into Great Britain, and, therefore, no better time could be chosen for the celebration. A Committee has been formed of those interested in the movement, and Mr. Richard Dean, V.M.H., Ranelagh Road, Ealing, has consented to act as Hon. Secretary and Treasurer. The first meeting of the Executive Committee was held at the Horticultural Club, Hotel Windsor, on Friday last, and we subjoin an official report of the proceedings.

The first General Committee meeting in connection with the Bicentenary Celebration of the Sweet Pea was held, by kind permission, in the Horticultural Club Room, Hotel Windsor, on Friday, January 19th, when Mr. George Gordon, V.M.H., presided over a very representative gathering.

Business being the purpose of the meeting no time was lost in speechifying. The Chairman briefly alluded to the desire expressed in 1899 by leading amateurs, nurserymen, seedsmen, and market growers that a comprehensive exhibition of Sweet Peas should be held during 1900, together with a conference, one duty of which should be the classification and selection of varieties. This desire led to a meeting in Edinburgh in September last, when Mr. Gordon (Chairman), Mr. H. J. Jones, and Mr. R. Dean (Secretary) were elected as a preliminary

committee to draw up a scheme for the celebration and submit it as early as possible to the General Committee. After this brief and formal statement, the Chairman requested the Secretary (Mr. R. Dean, V.M.H.) to read the letters received from the Crystal Palace Company and the Royal Aquarium Company. The former offered to accommodate the exhibition, provide the necessary conveniences for a conference meeting, and subscribe £20 to the prize fund. This being the best offer, it was agreed, on the proposal of Messrs. H. A. Needs and H. J. Wright, that the Bicentenary Celebration be held at the Crystal Palace, Sydenham, on July 20th and 21st, 1900, or as near those dates as could be conveniently arranged without clashing with other exhibitions.

Having settled the place and date of celebration as far as possible, the next point for discussion was the schedule of prizes, of which a preliminary draft had previously been communicated to the Vice-President and Committee. Before the discussion of classes and prizes a list of subscriptions received and promised up to date was submitted by the Secretary, amounting to nearly £90. As the whole of the subscriptions received were unsolicited, the Committee felt that the success of the undertaking was practically assured, believing that those interested in the most beautiful, useful, and fragrant of annual flowers, the Sweet Pea, would not fail to show their practical sympathy with the Committee's efforts as soon as affairs had received definite form. The schedule is a comprehensive one of twenty-eight classes, each with four, and some with five prizes, offered on a most liberal scale. Class by class the schedule was discussed, and numerous minor alterations made. Nineteen open classes are provided for cut blooms, all to be shown in vases, these including classes for forty-eight, thirty-six, and eighteen bunches, and thirteen classes for one bunch of a specified colour or colours. Four classes are limited to amateurs employing either one or no regular gardener, and then there is a division, open to all, consisting of five classes instituted for the purpose of demonstrating the value of Sweet Peas in all forms of decoration known to the florist's art. The total amount offered in prizes in the preliminary schedule exceeds £90, and this comparatively large sum should ensure a display of the most beautiful and instructive character.

Special prizes are invited, but they must, in accordance with the resolution passed at the Edinburgh meeting, be free from any trade conditions. Already several firms have intimated their intention of providing the prizes in certain classes, and at this meeting it was decided to accept Mr. Henry Eckford's generous offer of £15, the sum offered in Class 1 for forty-eight bunches of Sweet Peas in not less than thirty-six varieties, an offer made by the Wem veteran to commemorate the fact that this is the twenty-first year of his work in selecting and cross-fertilising Sweet Peas. Mr. H. J. Jones' offer to supply the prizes in Class 25, for an epergne of Sweet Peas, £2 17s.; and Mr. R. Sydenham's offer to supply the prizes in two of the amateur classes, amounting to upwards of £5, were accepted and acknowledged. With reference to the rules and regulations for competitors it is worth while noting that from subscribers of 10s. 6d. and upwards no entrance fees will be demanded, but non-subscribers must pay an entrance fee of 5s. to entitle them to compete in any six classes (subject to divisional schedule regulations), but a further entrance fee of 5s. must be paid if this number is exceeded.

Conference proceedings, subscribers' tickets, publication of report, and other matters were referred to, but reserved for final discussion and settlement at the Committee meeting to be held on Friday, February 23rd, by which date the complete schedules and regulations will be ready for acceptance and immediate publication.

Meanwhile the Committee desires the sympathy and financial assistance of all horticulturists, so that the forthcoming celebration may be made the unqualified success its interest and importance demands. Any surplus funds remaining after the payment of prizes and necessary expenses will be given to the gardening charities.

Further particulars can be obtained from the Hon. Secretary, Mr. R. Dean, V.M.H., Ranelagh Road, Ealing.

LIBONIAS.—In the middle of winter, when the Chrysanthemum is over, and forced plants are scarce, there is sometimes a difficulty in keeping the conservatory gay until spring flowering stock puts in an appearance. Among those that might be successfully grown to fill the gap, Libonias take a prominent place. There are two in cultivation—i.e., *floribunda* and *penrhosiensis*. The former is a Brazilian species, which makes a well furnished bush from 1 to 2 feet high, thickly clothed with small, light green leaves. The flowers are produced in abundance. They are about 1 inch long, and scarlet and yellow in colour. *L. penrhosiensis* is a hybrid between the above mentioned species and *Jacobinia Ghiesbreghtiana*, inheriting good qualities from both parents. It is sturdier in habit than *L. floribunda*, with larger, more acuminate leaves and bright red flowers. Libonias can be readily grown from cuttings in spring. From cuttings rooted in February good bushy plants from 9 to 15 inches high can be had by autumn. A mixture of loam, leaf soil, and decayed manure in equal proportions is suitable for the final potting; loam, leaf soil and sand for the former. By the beginning of June plants should be well established in flowering pots, when they ought to be stood outside until autumn. If the plants are cut back after flowering and started in a little heat, they can be kept for several years in good condition.—W. D.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—JANUARY 23RD.

THE Drill Hall was not particularly well filled with exhibits on Tuesday, but the Primulas in the floral section and the Orchids made a beautiful display. The latter were of exceptionally high quality.

FRUIT COMMITTEE.—Present: Geo. Bunyard, Esq. (in the chair); and Messrs. W. Poupart, J. Cheal, Jas. H. Veitch, A. H. Pearson, A. Dean, S. Mortimer, J. W. Bates, C. Herrin, G. Wythes, H. Balderston, J. Smith, G. Norman, J. Willard, and R. Fife.

Messrs. Sutton, Reading, staged four boxes of their new Tomato Winter Beauty; the fruits were excellent in colour, and of good size. Messrs. G. Bunyard & Co., Maidstone, showed an interesting display of Apples, which included the American variety Twenty Ounce, White Nonpareil, Farmer's Seedling, a beautiful dish; Belle de Pontoise, a good kitchen variety; Beauty of Kent, King of Tompkins County, Foster's Seedling, a cross from Blenheim and Cellini Pippin; and Rambour Papalen. Needless to say all were staged in the best possible condition. Several dishes of Apples were staged, but failed to secure any award or notice from the Committee. The Fruit Committee passed a vote of condolence with the family of the late Mr. R. D. Blackmore, who was for many years a member of that body.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); and Messrs. C. Druery, H. B. May, R. Dean, J. H. Fitt, Jas. Hudson, G. R. Fielder, Geo. Gordon, J. W. Barr, C. E. Shea, H. J. Cutbush, E. T. Cook, Chas. Blick, Geo. Paul, and J. Fraser (Kew).

Messrs. H. Cannell & Sons, Swanley, Kent, arranged a large table of single Primulas of varied colours. The plants were of dwarf habit, and all appeared to be robust. The most noteworthy varieties were White Lady, an excellent white with dark foliage; Dr. Nansen, a rosy red; Mrs. R. Cannell, a white with long footstalks and dark foliage; Duchess of Fife, a charming variety with pink flowers, very distinct; The Sirdar, a large salmon pink; Miss Dorris, a white with Fern-leaved foliage, and Swanley Blue.

A beautiful exhibit of Ferns was staged by Messrs. J. Hill & Son, Lower Edmonton, which embraced several well grown specimens, also a quantity of decorative Ferns. The best examples were *Asplenium caudatum*, *Gymnogramma peruviana cristata*, *G. schizophylla gloriosa*, *Nephrolepis multiceps*, and *Polypodium phymatodes*. The smaller plants of *Lastrea aristata variegata*, *Lastrea lepida*, *Adiantums* in variety, and *Pteris Victorice* were no less pleasing. Messrs. Hugh Low & Co., Bush Hill Park, staged a fine collection of *Cyclamen Papilio*, the white variety Bush Hill Pioneer, and the red form being well grown, while the mixed colours were particularly attractive. Messrs. Barr & Sons, Covent Garden, showed two bowls of the Sacred Lily of Japan, well developed and in good form. Messrs. Jas. Veitch and Sons, Ltd., Chelsea, sent a basket of *Hamamelis arborea*, with its quaint flowers, also a box of their beautiful hybrid *Rhododendrons* in good variety, the colours being exceedingly bright and varied. Mr. Jas. Hudson, gardener to L. de Rothschild, Esq., Acton, staged a fine vase of *Justicia flavicoma*, an attractive yellow flower that is welcome at this season.

ORCHID COMMITTEE.—Present: J. Gurney Fowler, Esq. (in the chair); and Messrs. J. O'Brien, Jas. Douglas, E. Hill, A. Hislop, A. H. Tracy, F. J. Thorne, W. H. Young, H. J. Chapman, J. T. Gabriel, F. Sander, de B. Crawshaw, H. T. Pitt, and W. H. White.

Mr. W. H. Young, Orchid grower to Sir Frederic Wigan, Bart., Clare Lawn, East Sheen, contributed a most beautiful group of *Phalenopsis*. The splendid spikes comprised many of the best known forms. From the same source also came a grand plant of *Dendrobium atro-vioaceum*, *Laelio-Cattleya callistoglossa Princess of Wales*, and a few other Orchids. Mr. J. Downes, gardener to J. T. Bennett-Poë, Esq., Cheshunt, showed a handsome specimen of *Laelia anceps Sanderiana* carrying four fine spikes. Messrs. Charlesworth & Co., Heaton, Bradford, staged *Laelio-Cattleya Sunray*, L.-C. Charlesworthi, L.-C. Cappei, and *Cypripedium Cowleyanum magnificum*.

A superb branching spike of *Odontoglossum crispum* came from Mr. Hill, gardener to Lord Rothschild, Tring, and *Dendrobium Galatea* from Mr. R. J. Thwaites, Christchurch Road, Streatham. Messrs. H. Low & Co., Bush Hill Park, sent *Phalenopsis Schilleriano-Stuartiana* and *P. intermedia Brymeriana*, with two forms of *Cymbidium Traceyanum*. Mr. H. Ballantine, gardener to Baron Schröder, The Dell, Egham, was represented by *Odontoglossum Wilckeanum Schröderianum* and *Dendrobium Vannerianum*. Mr. N. C. Cookson showed from Wylam-on-Tyne *Cypripedium Sanderiano-Curtisi*, or, as the officials of the Orchid Committee preferred it, *C. Somdenimo Curtisi*. Mr. Hislop, gardener to H. S. Leon, Esq., Bletchley, showed *Laelio-Cattleya Fanny Leon*.

Mr. J. Barker, gardener to W. Birkenshaw, Esq., Hesse, exhibited *Cypripedium nitens Hesse* variety and *Adrastus punctatum*, both handsome forms. *Cypripedium Mooreanum* and *Beckmanni* came from F. F. Moore, Esq., Bourton-on-the-Water, as did *Cattleya Percivalliana*, Chardwar var. *Odontoglossum crispum castum* was staged by Sir William Marriott, Bart., while *Odontoglossum Rossi* Mrs. de Barri Crawshaw, and O. R. Lionel Crawshaw came from Mr. de Barri Crawshaw, Sevenoaks. Messrs. F. Sander & Co. St. Albans, exhibited *Dendrobium Madonnæ* and a splendid plant of *D. atro-vioaceum*.

Messrs. J. Veitch & Sons, Ltd., Chelsea, contributed a charming group of Orchids, in which *Cypripediums* played a very conspicuous

part. These included *Niobe*, *Euryades* in variety, *Lathamianum*, *Actæus*, *vexillarium*, *Charles Canham*, *Leeanum*, *Æson*, *Godseffianum*, *Pharos*, and *Harrisianum superbum*. *Dendrobiums* were represented by *Findlayanum*, *Dulce*, *atro-vioaceum*, *Cassiope*, and *Endocharis*. There were also *Laelia* Mrs. M. Gratrix, L. Mrs. M. Gratrix *superba*, *Laelio-Cattleya Pallas*, *Cypripedium Actæus langleyense*, *Phaio-Calanthe insperata*, and *Epidendrum Wallisio-ciliare superbum*.

Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart., Dorking, exhibited *Dendrobiums burfordiense*, *melanodiscus Rainbow*, and *Cordelia* with *Tainia Penangiana*, *Maxillaria leptosepala*, *M. arachnites*, *Epidendrum amplexicanle*, *Cypripedium Sallieri-Hyeaunum*, *C. Leeaunum Albertianum*, and *Calanthe Regneri hololeuca*.

MEDALS.—Large exhibits were not particularly numerous on this occasion, and medals were not therefore abundantly awarded. Floral Committee: silver Flora medals to Messrs. H. Cannell & Sons and J. Hill & Son; and silver Banksian medal to Messrs. H. Low & Co. Orchid Committee: silver Flora medal to Mr. W. H. Young.

CERTIFICATES AND AWARDS OF MERIT.

Apple Hornead's Pearmain (G. Bunyard & Co.).—An excellent Apple, that is comparatively well known and highly appreciated (award of merit).

Apple Norman's Pippin (G. Bunyard & Co.).—Not a particularly attractive fruit. It is uniform greenish yellow, with profuse markings of russet. The eye is deeply set, and the long thin stalk is inserted in a round cavity (award of merit).

Calanthe Regneri hololeuca (W. H. White).—A pure white variety of chaste beauty (award of merit).

Cypripedium Actæus langleyense (J. Veitch & Sons).—This is a hybrid from a cross between *C. insigne Sanderæ* and *C. Leeaunum*. The petals are very pale green, with a tinge of yellow. The pouch is yellowish green. The handsome dorsal sepal is white, with a green base and sparse purple spots (award of merit).

Cypripedium Sanderiano-Curtisi (N. C. Cookson).—This is a beautiful hybrid. The prevailing colour is deep claret, the long petals being profusely spotted. The dorsal sepal is greenish white with purple stripes (first-class certificate).

Epidendrum Wallisio-ciliare superbum (J. Veitch & Sons).—A grand variety. The stout sepals are intense deep yellow, and the petals are slightly paler. The splendid lip is white with purple markings (first-class certificate).

Laelia Mrs. M. Gratrix *superba* (J. Veitch & Sons).—A very much improved form of the type represented in the engraving, fig. 71, page 377, last vol. (award of merit).

Laelio-Cattleya callistoglossa Princess of Wales (W. H. Young).—A very beautiful pale coloured form of the well known bigener (award of merit).

Laelio-Cattleya Charlesworthi (Charlesworth & Co.).—A handsome hybrid from *Laelia cinnabarina* and *Cattleya aurea*. The petals are deep brick red, and the sepals are of slightly lighter shade. The lip is reddish maroon (award of merit).

Laelio-Cattleya Fanny Leon (W. Hislop).—No parentage was given of this bigener hybrid. The sepals and petals are rose purple, and the lip is velvety maroon with a paler margin (award of merit).

Laelio-Cattleya Sunray (Charlesworth & Co.).—This resulted from a cross between *Laelia cinnabarina* and *Cattleya superba*. The sepals and petals are cinnamon yellow, lighter in the first named; the lip is velvety purple crimson (award of merit).

Phalenopsis intermedia Brymeriana (H. Low & Co.).—A most attractive flower. The sepals and petals are white tinged with rose, and the lip is deep crimson (award of merit).

Phalenopsis Schilleriano-Stuartiana (H. Low & Co.).—A most attractive flower. The broad petals are white with deep rose in the centre, as is the upper sepal; the lower sepals are white with rose spots and suffusion, as is the lip (first-class certificate).

Rhododendron multicolor Triton (J. Veitch & Sons).—A salmon pink variety of great beauty (award of merit).

THE NEGLECT OF FLOWERING SHRUBS IN OUR GARDENS.

This was the subject of a discourse delivered at the afternoon meeting in the Drill Hall by Mr. G. Bunyard, V.M.H. The attendance was not so large as might have been wished, but those present were evidently interested in the remarks. It was not, as is generally the case, a set essay, but a dissertation from notes. The subject is one that has been frequently treated of in the horticultural press, but, so far as small gardens are concerned, with little apparent effect, and it is to be hoped that Mr. Bunyard's views when embodied in an article and reproduced in the Journal of the Royal Horticultural Society will be productive of immediate and lasting good. Needless to say, the lecturer dealt with his subject in a masterly manner.

CARNATION MRS. THOS. W. LAWSON.—We are informed that Mr. Thomas F. Galvin has received orders for over 300,000 rooted plants of the famous 30,000-dollar Carnation. Considering the fact that it is barely three months since the announcement was made that the cuttings would be placed on the market, the amount of the orders received to date is phenomenal. The plants will be ready for delivery after February 1st, and it is advisable that orders should be forwarded at once to Mr. Galvin, 124, Tremont Street, Boston, Mass.

THE YOUNG GARDENERS' DOMAIN.

BITS FOR THE BOTHY.

TO OUR RECRUITS.

ERE the strains of the new year's march are lost in the din of more pressing engagements as days lengthen and work increases, one would fain marshal a few thoughts in review order for our boys of the bothy brigade. Not only is the present time apparently opportune to do so, but since "An Old Boy" exercised the young ones on the drill ground of this "Domain," not a few must have received their commissions and gone to the front in the great battle of life. In the common sequence of things there must be many fresh faces in the ranks, those who have lately "listed" under the glorious banner of imterior Nature, whose orb is the sun, whose sceptre is the elements. Unfortunately there is no new drill book to claim attention by the charms which novelty ever possesses, but the endeavour shall be made to introduce fresh illustrations to point that moral which is its superscription—duty—viz., duty to your vocation and duty to yourselves, two separate parts but inseparably bound up in the single volume of a gardener's life.

Few, perhaps, realise the importance of gardening in the great problem of life. In its rapid growth and far reaching influence, however, there are not wanting signs for the seer to interpret and predict its eventual development into the highest, and possibly the noblest of man's administrative works; to remain as such when huge armies, gigantic navies, and the diamond mines of Africa have passed from memory as things no longer worth remembering. "That's going a long way ahead," some will say. That is so. It goes eventually as far as Nature goes, and when and where she stops all things end and time is a forgotten circumstance. One would like (but how feeble must be the attempt) to impress upon those who have chosen the good life of a gardener, the beauty, and purpose, and power of this great empire of Nature. Alas! It cannot be, "for this great scene thought is too low, and majesty too mean." If the precocity of youth demands something more practical. Emerson says, "The mind that is parallel with the laws of Nature will be in the current of events, and strong with their strength."

"Gardening is a tame sort of business" has been said. It is a libel on it and on Nature. "People are so practical nowadays; they want plenty of Potatoes, and a very little philosophy will go a long way." True, but it seldom goes far enough to show things as they are and not what they seem. There is more complex mechanism and comparative power in a bursting bud than in a lyddite shell; but there is an epidemic of moral blindness about which shuts people's eyes to the fact, not to speak of that mock modesty abroad which would clothe the naked truth in the khaki of shoddy reasoning, and prostitute the infinite into the fashion of an hour. But enough, if sufficient has been said to prevent any young fellow from even thinking that his life's work before him can ever be "tame."

Congratulations to each recruit now toeing the gardening line at the dawn of the twentieth century. From this eminence what a glorious vista of possibilities opens out. As for the present, we elders cannot help feeling a little regret that fate had not postponed our advent upon this planet until we could have been dropped down, just as they have been, among the marvels of Marconi telegraphs, pneumatic wheels, electric lighted stokeholes, telephone in the potting shed (all accomplished facts), and all the blessings of this life which are ready to hand. But above and beyond such brilliant things as tend to throw into deep shadow the decades of one's early days is that recognition of the recruit as an important factor in the noble army of gardeners. Veterans of to-day realise the value of such things by reason of their own impoverished youth when some gardens were to them only a kind of work-house, governed by such poor laws as left lads veritable paupers so far as sympathy with their aspirations, and encouragement generally, were concerned.

That things were not wholly bad in the days of auld lang syne is admitted, but somehow it was more the mailed fist than the hand of friendship which governed in the garden. How pleasant it is now to see a master impress good counsel by a friendly hand laid on a lad's shoulder as against that grip of the ear old boys enjoyed (?) as it was forcibly wrung to emphasise the vituperative poured into it by the vials of wrath! Exaggerated? No. In one large garden such things were almost of daily occurrence, and during summer, when half a dozen boys were employed pulling Peas or picking fruit, unearthly yells were often heard from lads who had momentarily mistaken a mouth for a basket. Nor was the bothy exempt, as witness that auricular demonstration between "t' gaffer" and a comrade who had stoned his dog, a vicious brute whose partiality for calves was second only to his master's fondness for ears. How it all flashes again through the cinematograph of memory! The "gaffer" dogging him to the bothy and running him to earth in the kitchen, where half a dozen of us witnessed the humiliating spectacle of M—— being pinned by both ears from the rear as he was lustily kicked from the same direction, to a duet of chin music by both master and man.

1900 brings with it such a hurrying of feet for the front that it seems wasted time to pause and ponder over the past. More haste, less speed, however. Going back a brief space gives an impetus for getting on. This worrying spirit of the age seems to lash its victims into a fury of haste to reach the goal of their ambition, and some of our recruits seem pretty badly infected with it too. There seems to be

a dread of bothy life (that dear old bothy life!) absorbing too large a share of the threescore years and ten; or is it that they think themselves so beloved of the gods as likely to die young, or what is it? One can scarcely account for this restlessness in bothydom. Here is a very bad case in point. He is two-and-twenty, bright, active, and intelligent, and loves his work. All this, and more also, marked him as one for whom all sorts of good things were predicted. "And what has he done?" you will ask. Well, his own words answer that, as he said, "I've got the 'missus,'" in presenting her whom we had supposed to be his sister. "Had to leave So-and-so; Mr. — wouldn't keep a married mau (boy we mean) in the bothy." And now he is looking for a situation; they were both looking, and "knew they had a friend in"—THE OLD BRIGADIER.

(To be continued.)

FRUIT FORCING.

Vines.—*Early Forced in Pots.*—Thin the berries somewhat freely as soon as well set, so as to secure large ones, yet not to the extent of making the bunches loose and unshapely. Maintain the night temperature at 65°, falling to 60° on cold mornings, but raise the heat early to 65° or 70°, keeping at 70° to 75° by day, increasing to 80° or 85° with sun heat, and closing at 80°, with a prospect of an advance to 85° or 90°. Ventilate very carefully, always early, closing in good time, then damping the house. Sprinkling is also necessary early in the day. Afford copious supplies of tepid liquid manure.

Early Forced House.—Duplicate and superfluous bunches should be removed, and the berries thinned as soon as they become well formed, not deferring it beyond the distinguishing of the fertilised from the unfertilised. The inside border may be covered about an inch thick with sweetened short stable manure, which should be turned several times before it is introduced, otherwise the ammonia evolved may prove injurious to vegetation. Attention will be required in tying the shoots and in stopping the laterals. Where space is restricted the shoots may be stopped closely, say one joint beyond the bunch, and the laterals be pinched at every joint as made. In other cases more growth may be allowed, but in all it is important that the principal leaves have full exposure to light and air.

Vines in Flower.—When coming into bloom maintain the night temperature at 65°, 70° to 75° by day, 5° to 10° more from sun heat. Muscat of Alexandria and all the shy setting varieties should have 5° more, and the bunches should have all the light possible, and their ends facing the sun, then when in flower they can be rapped on the stem gently, or better have the pollen dispersed on the stigmas by using a camel's-hair brush charged with pollen from free setting varieties. A constant circulation of warm, rather dry air is conducive to a good set, and it is advisable not to stop the growth closely during the setting period.

Vines Started at the New Year.—Continue syringing the rods twice a day, but do not keep them constantly wet, as this induces aerial roots from them, and interferes with proper root formation. Syringing may be continued until the bunches show, but then damping the borders and paths two or three times a day will be necessary to maintain a genial condition of the atmosphere. Do not be in a hurry to disbud, letting the growths advance until the bunches appear in the points of the shoots, then the weaker and otherwise less desirable can be removed; but it should be done gradually, so as not to cause an appreciable check.

Vines to Afford Ripe Grapes in July.—The beginning of February is the latest time for starting midseason varieties to finish after midsummer. Outside borders, even where the roots of the Vines are entirely outside, need not be covered with fermenting materials, but a covering of leaves with a little litter over them to prevent them blowing about is all that is necessary to prevent the soil becoming frozen. The stems of the Vines, if outside, must also be thoroughly protected by haybands wrapped round them. Maintain a minimum temperature of 50° and allow an advance to 65° from sun heat, 55° being the maximum from fire heat in the daytime. This will cause the sap to rise steadily, and a light damping occasionally promotes the osmotic action of the cells, and the transference of stored matter from the wood to the growing parts. Due moisture at the roots is also imperative, for though the moisture may not be excessive some is necessary. Therefore moisten the border through to the drainage, using water very slightly in advance of that of the house in temperature, and if the Vines are weakly and the border in good order afford liquid manure after the moistening of the soil, which will to some extent displace the water and afford nutriment in due time.

Eyes and Cut-backs.—Eyes may now be inserted, using pots, pans, or square pieces of turf. Select plump buds on firm well-ripened

wood, filling the pot or pan with rich friable loam; insert the eyes with a pinch of silver sand, and about half an inch beneath the surface. Plunge the pots in a bottom heat of 80°. Cut-backs should be placed in a house where they will have a temperature of 60° to 65° at night and 70° by 75° by day. When they have started into growth shake them out, and return to the same size of pot, using good friable loam, and give a rather close and moist atmosphere until re-established, when they should have a position near the glass, so as to insure sturdy, short-jointed, thoroughly solidified growth.

Strawberries in Pots.—The November started plants have set the fruits fairly well, and are swelling the six to a dozen berries per plant freely. The December plants being brought on slowly are advanced for flowering, when they should be freely ventilated, have the weaker flowers removed, and the pollen distributed with a feather as soon as ripe. After the fruit is set thin them to the number the plant is likely to swell perfectly. Whilst the fruit is setting 50° to 55° will be sufficient heat artificially, and 60° to 65° by day with sun heat, but after the setting is effected remove the plants to a house with a temperature of 60° to 65° at night and 70° to 75° by day, supplying liquid manure until ripening commences; then employ water only and sparingly. Whilst swelling they require a moist genial atmosphere.

Successional plants must not lack water, but needless watering is highly prejudicial, therefore examine each plant, and afford a supply only when required. The plants succeed best when brought on gently, a temperature of 50° from fire heat being ample. Examine the plants carefully for aphides, and if there be any trace fumigate moderately, taking care to have the plants perfectly clean before they come into flower. Introduce more plants for succession.

THE KITCHEN GARDEN.

Cauliflower.—If the stock of autumn-raised plants is too limited, more seed ought to be sown now. The small so-called forcing varieties are the quickest to heart-in, and with these may be raised successional and late varieties, including Autumn Giant. The seeds should be sown thinly in boxes of fresh loamy soil, and be placed in gentle heat to germinate. Be careful not to syringe the seedlings, as this may encourage damping. Before they become much drawn place the plants on shelves near the glass in a warm greenhouse. The stems must become moderately firm before the plants are placed singly in small pots. Cauliflowers in frames and hand-lights should have the soil about them stirred, and a dusting with dry ashes to ward off slugs.

Celery.—If very early Celery is wanted seeds of a good white variety may be sown at once thinly in pans of fine soil placed in a brisk, moist heat, covered with squares of glass, and shaded heavily. The soil must be kept uniformly moist, and this can best be done without disturbing the seeds by partially immersing the pans as often as necessary in tepid water. Celery that has already been crippled somewhat by frost stands in the greatest need of protection afterwards.

Leeks.—If fine Leeks are wanted in the summer seeds of a good exhibition variety should be sown now, thinly in pans, and placed in heat to germinate. In many gardens green vegetables are becoming somewhat scarce, and the Leeks, hitherto somewhat despised, will soon be more appreciated.

Lettuce.—Slugs have cleared off autumn raised plants wholesale, it being next to impossible to save them during the long spell of wet and comparatively mild weather. Luckily plants of Early Paris Market and Golden Queen Cabbage varieties, raised early in the year, heart in very quickly, so that the loss of autumn raised plants will not be felt by those who sow seed promptly and place them in gentle heat to germinate. Directly the seedlings are through put the pans or boxes on shelves near to the glass. If plants of the varieties named have been kept through the winter they may be gently forced either in boxes of rich loamy soil in a light position in a vinery or Peach house, or a mild hotbed may be prepared.

Tomatoes.—Autumn raised plants are the best for producing early crops of fruit. They ought not, however, to be kept in small pots long enough to become leggy and hard in the stems, as when in such a plight they seldom develop into stout productive plants. Pot culture answers best in the case of early crops, and the plants may be shifted straight from 3-inch pots into the fruiting sizes—10-inch to 12-inch. The best positions are the fronts of small forcing houses, arranging the pots closely together on a bed of soil or ashes, into which the Tomatoes may eventually send their roots, and training the plants, confining them to single stems, straight up the roofs. Fill the pots with rich loamy compost, and when it is well warmed through plant in this, making the soil somewhat firm. Not much water should be given at first, but later water or liquid manure will be required daily. If preferred the plants may be put out in a narrow ridge of soil much as Cucumbers are planted, adding compost occasionally in the shape of top-dressings. Very high temperatures are a mistake. From 55° to 60° and 65° is quite hot enough. When the plants are growing strongly give a little top air on warm days.

Sowing Tomato Seed.—Plants obtained by sowing seed now will, if properly managed, produce the heaviest crops of all. Sow seeds of approved varieties thinly, or singly, as this is almost the only way to avoid having too many plants, in pans or boxes of light sandy soil, and place in heat to germinate. Before the seedlings become leggy raise the pans or boxes well up to the glass, and when rough leaves have formed, put the plants singly in 3-inch pots.

THE BEE-KEEPER.

BEES IN WINTER.

It is interesting to observe the condition of the bees in winter as well as in summer. Not that we recommend a general overhauling of the stocks at this season, when the temperature is low and the bees are in a state of stupor. It is, however, only by making an examination of the various colonies that we are enabled to form a correct opinion as to their condition and the position the bees occupy in the hive. During a recent spell of mild weather, when the temperature was several degrees above freezing point, but not warm enough for the bees to be on the wing, we examined several strong colonies in straw skeps as well as those warmly housed in wooden hives. In many instances the skeps had not been lifted from their stands since the swarms were placed in them in the summer, consequently they were firmly secured to the floor board with propolis.

Before attempting to lift the skeps an old table knife was passed under the lower rim of straw; the hives were then lifted without any trouble. In replacing them on the floor board care was taken to put them in exactly the same position they previously occupied. No undue ventilation was afforded them from the sides, as the entrances had been left open their full width throughout the winter. In the majority of instances we found the bees clustered close to the side of the skeps in a state of stupor.

This fact will probably come as a surprise to many bee-keepers, as the bees are usually supposed to be in the middle of the hive. This is the position they occupy in the modern wooden frame hive; at least such was the case with those we examined, as there was not a single instance of the bees being clustered on the side combs.

What are the lessons to be learnt from the above? We think there cannot be two opinions on the subject. It was owing to the straw being warmer than the wood that the bees clustered in the manner they were found. In each case the hives were well protected; the majority of the frame hives had double sides, the extra coverings being on the top of the frames. Thus the bees clustered on the middle combs, which was doubtless the warmest part of the hive.

HIVES FOR GENERAL USE.

Bearing the above facts in mind, it may be an advantage to ask which are the best hives for general use? Although straw may be warmer than wood, it does not follow that more honey will be obtained from a stock of bees placed in a straw hive than would be secured had they been in a hive made solely of wood. Bee-keepers are fully alive to the fact that one of the chief essentials to successful wintering is a warm, dry hive. But for various reasons straw is not adapted for frame hives. Although we have seen it successfully used in conjunction with wood for that purpose, the sides being made of straw, and the corners, bottom, and roof of wood. They had a neat appearance, and bees invariably wintered well in them.

The best hive we consider for general use is the one that any handy man may make in his spare time. All that is necessary is to have a pattern to work from, and this is best obtained by procuring a good hive from a bee-keeper or a tradesman who deals in bee appliances, and make others like it, care being taken that the measurements are correct. If all the hives are made after the same pattern much valuable time will be afterwards saved in the practical management of bees.

Choose a hive holding ten, or, at the most, twelve standard sized frames. The sides should be double, having an air space which may be left open throughout the year, or be filled with cork dust in the winter. This can be removed in late spring, as the open air space at the sides will be beneficial to the bees during the prevalence of hot weather. It is doubtful whether it is worth the labour of filling the sides of the hive with cork dust or some other material for wintering purposes, as with double sides bees invariably winter well when this air space is left open throughout the year.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Punnets (Roons).—We regret to be unable to comply with your request. We are not in possession of any addresses such as you require. Cannot you obtain them by inquiries in the Leeds vegetable market?

English Paradise Stocks for Grafting in March (M. D.).—The stocks may be procured of any large nurseryman, especially those making fruit tree raising a specialty, by the 100 or 1000, at moderate prices. Write to one or more of the nurserymen advertising in our columns, stating requirements, and asking for quotation of price. The stocks now or shortly procured would hardly be fit to graft in March or early April next, as they will not have become established sufficiently to induce a vigorous growth in the grafts. The stocks would be all the better for growing a year before they were grafted, or they will be well rooted by the July following the planting, and could then be budded satisfactorily.

Fly and Spot in Cattleyas (C. A., Yorks).—The young leads of Cattleya you send are badly infested with Cattleya fly, a most pernicious pest that is usually introduced among newly imported Cattleyas and Lælias. Its effect is first to cause an abnormal swelling (fig. 18) of the buds (breaks), and afterwards to completely paralyse their growth, as in your case. The female fly punctures the soft tender growth, and lays the eggs that eventually form the grubs that do the mischief. There is no cure after the grub is ensconced in the living tissues of the plant, and every growth seen to be affected must be cut off at once. The affected buds can easily be detected by the swelling referred to. Occasional fumigations with XL All insecticide kill the female flies that may be in the house, and is in this way a certain preventive, and must be persisted in. You need be under no apprehension as to the result of cutting away the buds; only do it early enough, so that the plant has time to form back breaks, which will probably be clean. The swelling in the leaf is the dreaded "spot" (fig. 19) that has ruined thousands of Orchids. Cutting away and burning the worst affected leaves, and the maintenance of a genial atmosphere about the plants are the only remedies, and these are only partial. Sometimes the plants grow out of it, but usually they take a long time. If you have only a few plants as badly damaged as the leaves sent it would be advisable to burn them. We found several flies in the bottom

FIG. 18.
FLY IN CATTLEYA.

of the box, and advise you to fumigate the house in which the plants are growing with all speed. For the two illustrations from "The Flower Grower's Guide" we are indebted to the courtesy of Messrs. H. Virtue & Co., Ltd.

Rating of Vinery and Tomato House (Milton).—In answer to your question whether you are liable to pay rates for greenhouses or not, we may quote the following from our columns of August 10th, 1899, page 123:—"Judgment was given, on Thursday, by the Lord Chancellor, in the House of Lords, in an appeal which raised the question whether market and nursery gardens, upon which are greenhouses and other structures used for productive purposes, can claim the benefit of the Agricultural Rating Act of 1896, which relieves the occupier of agricultural land of half the rates in respect of the hereditaments and buildings upon the holding. At Worthing the overseers had returned a market garden and the structures upon it as agricultural land, but the surveyor of taxes treated them as buildings. The question was carried by way of appeal through the courts, and the noble and learned Lords now affirmed the judgment of the Court of Appeal, that a market garden with its buildings is not agricultural land within the meaning of the Act." You will perceive from the foregoing that you are not only liable to pay rates for greenhouses, though you are growing only for market, but cannot claim the benefit of the Agricultural Rating Act of 1896, which relieves the occupier of agricultural land of half the rates in respect of the hereditaments and buildings upon his holding.

Cavities in Apple Tree Twigs (W. K.).—The holes or scars on the Apple tree twigs are different from those caused by woolly aphis, and so peculiar, that we may at some future time portray the scarred appearance of the Apple twigs. The holes are caused by an insect called the buffalo tree hopper (*Ceresa bubalus*), which does not live, as a rule, on orchard trees, but develops on succulent vegetation; hence is most destructive in orchards and plantations, where weeds and other tender herbage are abundant. The scars are due to the egg punctures of the insect. The eggs are laid in the upper part of the young twigs of Apple, Pear, and various other trees, mostly during the late summer and early autumn months, being arranged in two nearly parallel or slightly curved slits, extending in the direction of the twig about 3-16ths of an inch in length, and separated by 1-8th inch or less of bark. In making the second slit the insect cuts the bark obliquely, in such a way as to leave a small piece loose. This causes the bark to die, and eventually leaves a dead space and hollow in the twig. These dead spots give the bark a cankerous appearance, and are excellent places for bark-fungi spores to germinate in. The eggs of the insect remain dormant until spring, then the small, active, greenish hoppers are hatched out, and they become full grown about the middle of summer. The limiting of weeds and other vegetation of a tender nature about orchards and fruit plantations, as well as in them, is an excellent precaution, little damage occurring where the ground is kept clean. In badly infested cases pruning is advisable, and as there are some scale on the twigs, spraying with a solution of caustic soda and pearlash, $\frac{1}{2}$ lb. each to 6 gallons of water, at a temperature of 130°, whilst the trees are quite dormant, would be serviceable. In the spring, treatment with petroleum emulsion could not but be useful against the hoppers and other pests.

FIG. 19.
SPOT IN CATTLEYA.

Mixing Burnt Clay with Strong Loam for Rhododendrons (J. D.).—If your statement as to the nature of the land and the treatment to which it has been subjected is quite accurate, and if the loam contains a large percentage of gritty particles or the mud a considerable amount of silt or sandy or gravelly matter, the Rhododendrons will grow well, as the gritty matter will keep it open and sweet. On the other hand, if the loam be of a close nature and mud, ordinary pond accumulation with tree leaves, a sort of bog soil, the mixture of strong loam with pond mud would be greatly improved by adding burnt clay to it, say a fourth or not more than one-third. The burnt clay would tend to render the compost more open and correct any not unlikely organic acids resulting from the decomposition and settling of the pond mud into a close sour mass. Rhododendrons love moisture, but they do not thrive on a wet, cold, sour base. Burnt clay has a strong affinity for water, and though used for foundations of walks, holds or absorbs moisture in dry periods, so there is no need to fear anything from over-dryness, especially as the subsoil is clay. Pond mud in woody districts is largely composed of vegetable mould. Once we cleared out a morass of several acres, this being a former sheet of water silted up and choked by aquatic plants, threw the mud into large mounds of irregular form and in picturesque order, and in due course planted them with Rhododendrons and Azaleas, and had a grand American garden, the soil underneath being a stiff clay, in which Rhododendrons did not thrive. No greater mistake is made than digging pits for Rhododendrons and other American or peat loving plants. It is far better, especially in the case of clays, to raise mounds and plant on them, thus giving the stock the benefit of the cool base and the eye a far better prospect, as the hill-and-dale arrangement is more pleasing than a non-undulating surface.

Fixing a Trentham Boiler (*Ignoramus*).—Almost any bricklayer could fix this simple and excellent boiler. We could not give details of the process from start to finish without diagrams. These would probably be furnished by the supplier of the boiler, or at least he would give you the details you require on application.

Ornamental Grasses (*Tyro*).—The following are about 2 feet high and less:—*Agrostis dulcis* and *nebulosa*; *Briza major*; *Bromus briziformis*; *Chrysurus aureus*; *Coix lachryma*; *Eragrostis elegans* (Love Grass); *Hordeum jubatum*; *Lagurus ovatus*; *Paspalum elegans*; *Pennisetum longistylum*; and *Stipa pennata* (Feather Grass).

Names of Fruits.—*Notice.*—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless Apples and Pears sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. Dessert Pears cannot be named in a hard green state. The practice of pinning numbers to the eyes of the fruits tends to destroy one of the most characteristic features and increases the difficulty of identification. When Plums are sent to be named young wood of the trees should accompany them. Leaves of the trees are necessary with Peaches and Nectarines, with information as to whether the flowers are large or small. (W. J.).—1, Gloria Mundi; 2, Bess Pool; 3, Court Pendu Plat; 4, Ribston Pippin. (B. L.).—Catillac. (N. F.).—1, Dumelow's Seedling, known also as Wellington and Normanton Wonder; 2, Red Winter Calville; 3, Northern Greening; 4, Bramley's Seedling; 5, Warner's King; 6, Blenheim Pippin. (Loughgall).—1, White Nonpareil; 2, Lord Hindlip; 3, Court of Wick; 4, Royal Russet; 5, unknown, probably a local seedling.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (P. F.).—1, Maranta Veitchi; 2, Tradescantia zebrina; 3, Peperomia argyrea variegata. The three Crotons can only be accurately named by comparison in a large collection. (H. O. N.).—1, Trichomanes radicans; 2, Microlepia hirta cristata; 3, Trichomanes reniforme; 4, Adiantum cuneatum var. (C. W. B.).—1, Cyperus natalensis; 2, Acacia longifolia; 3, Euonymus latifolius variegatus; 4, Thuiopsis dolabrata; 5, Cupressus Lawsoniana, seedling form. (O. M.).—Platyclinis (Dendrochilum) glumaceum.

POTATO EXPERIMENTS IN CHESHIRE.

THE Cheshire County Council is an enterprising body, and the Agricultural School at Holmes Chapel is conducted in a most admirable way. Very extensive experiments are carried on, and in such variety that it is impossible to notice all in the scope of a short article, but we propose to make some observations on the success or otherwise of several that have been made in the growth of Potatoes, and which appear to us to deserve attention. There is one point we should like to suggest to Mr. Gordon, the able Director, and it is this—an omission is made in the report which might easily be fulfilled next year. Every characteristic of the different varieties is mentioned except the strength of the haulm. The relative length and strength of the haulm in connection with either early or late ripening is a very important point, and one which men of experience would insist on knowing before investing largely in any variety.

There is a great deal that is interesting in these experiments, in fact a plethora of information. The results which attract our attention the most are those which confirm our own experience, and those which apparently contradict themselves.

We notice that in the larger experiments with a few of the varieties tried in 1898, the results come out very much as in that year, the exceptions proving a rule—i.e., that varieties of robust growth stand drought better than those with weak haulm. Almost the most interesting are the trials with various sized sets. There were six sizes tried, averaging respectively 1 inch diameter, 1½ inch whole, 1½ inch cut in two, 1½ inch, 1½ inch, and 2½ inch. The weights were respectively 1 oz., 1.37 oz., 0.68 oz., 2.6 oz., 3.9 oz., and 5.4 oz. The gross results were 11 tons 15 cwt. 3 lbs.; 12 tons 13 cwt. 1 lb.; 10 tons 13 cwt. 2 lbs.; 12 tons 18 cwt.; 13 tons 1 cwt.; and 13 tons.

18 cwt. 1 lb. It is clearly shown here that the produce increases with the size of the original plant up to a certain point, from which the gain is proportionately less, and consists of smaller and less valuable Potatoes.

If we take the weight of 1 oz. sets to plant an acre to be 10 cwt., then the weight of 5.4 oz. sets the same distance apart would be 2 tons 15 cwt, or 2 tons 5 cwt. more, whereas the increased produce is only 2 tons 2 cwt. 2 lbs. The largest proportionate gain is shown by the 2.6 oz. sets, which require 16 cwt. more to plant an acre, and produced more by 1 ton 3 cwt. The "Maincrop," the variety used for these trials is not a very robust grower, having a large number of weak but tall and fairly erect stems. We do not consider it a typical variety for a trial of this kind, and think that it would do the best from seed of about 6 oz. cut in two.

One useful lesson we may learn, which is that large-sized seed will pay when the seed is cheap, but under dearer conditions we must practise economy by sparing the sets if we have to increase the manure bill. We may be wrong, but we think that if trials of different sized sets had been carried out with three varieties instead of one, the lesson would have been more instructive.

Many trials were conducted with different manures, and with farmyard *versus* artificial manures. It was proved that artificial manures largely increased the crop, but not so much so as farmyard manure. To use the words of the report:—"The effect of farmyard manure shows clearly that the yield of crop does not depend entirely on the chemical ingredients used, but that the mechanical condition of the soil influences the yield to a large extent."

Sulphate of ammonia, in conjunction with farmyard manure and superphosphate, gave better results than nitrate of soda under the same conditions, and produced 28½ cwt. more saleable Potatoes than nitrate. This we should have expected. Nitrate applied at planting gave slightly better returns than when applied before earthing. Sulphate of ammonia at planting time would probably have done much better than either.

The most curious results are found in connection with the use of potash. Two forms were applied—kainit and muriate of potash. Five cwt. of kainit produced 23½ cwt. less Potatoes than 1 cwt. of muriate; but 2 cwt. of muriate produced 3 tons less 1 cwt. All three experiments were tried in conjunction with farmyard manure—nitrogenous and phosphatic manures. There is something very strange in these results, and we fancy we can account for them, although the Cheshire authorities pass them over without remark. The land on which the trials were made had been sown with Oats the previous year, having been in grass for eighty years, and we are told that there was a large quantity of old sod not decomposed when the Potatoes were planted. Thus with the addition of muck, nitrate and super, the land must have been in very high condition, and the addition of the potash would make very little difference, and especially the kainit, which would not be in a very assimilable form; but why should the increase of the muriate do absolute harm? We think this may be attributed to the muriatic acid.

We ourselves some time ago tried kainit, 4 cwt. per acre, against muriate of potash, 1 cwt., for Turnips, and with a view to a succeeding crop of Potatoes. A strip between the two plots was untilled. The kainit plot produced a slightly better crop than the untilled, but the muriate plot was far worse; the young plants were so long coming to the hoe. This we attributed to the bad influence of the muriate; but it did not extend to the Potato crop, which was satisfactory on both plots. Thirty years ago we saw similar bad results follow heavy applications of muriate of ammonia to Potatoes; 4 or 5 cwt. per acre was the quantity used, and other fields were dressed with similar quantities of sulphate of ammonia. The effects of the muriate were so very unsatisfactory that it was never tried again.

Another interesting trial was that between sulphate of ammonia and nitrate of soda as to their influence on foliage, size, and cooking quality of the crop. Sulphate was superior in producing better haulm and size of tubers, whilst the cooking quality was very good. Nitrate produced very pasty, dark-ended Potatoes.

Three important conclusions may be drawn from the trials:—

- 1, Large seed is more profitable than small seed.
- 2, Care must be exercised not to use muriate of potash in too large quantities.
- 3, Sulphate of ammonia is the best form of nitrogen to apply to Potatoes.

The yield per acre is less than last year's in almost every Potato tried.

We congratulate Mr. Gordon again on the success of such exhaustive experiments, which must have entailed so much labour and trouble.

WORK ON THE HOME FARM.

The weather keeps mild, but is very wet, and the land is quite unapproachable with horses. Farmers are here and there cross-cutting their fallows, but the horses would in most cases be better in the stable. The rain has hindered thrashing, but the smaller supplies of English grain have done the markets no good. We see published statistics showing that the visible supply of Wheat is larger than it has been for four years, so there is not much encouragement for farmers to hold.

Lair for sheep on Turnips is very bad. Many flocks are now on grass receiving a mixture of Swedes and Mangold, with hay and an extra allowance of cake. As Swedes are so scarce this is good policy, although the Turnip land will be robbed of a portion of the manure. Its mechanical condition, however, will be better for the absence of the sheep during such a wet time, and possibly may fully compensate in the Barley crop.

Breeding ewes on Turnips are a rare sight this year, and we suppose there will be a fortunate lambing season as a consequence. Preparations for the lambing must soon be made, and as we have remarked before, if possible a new site must be chosen for the lambing yard. When the farmer is fortunate enough to possess a roomy stackyard it may be usefully employed, if one side has been cleared of stacks, as the site, particularly if some straw stacks have been placed in such positions as to give shelter from the north and north-east. Straw may also have been stacked in an old seed field with a view to a lamb pen, so as to get a sweet lair for the ewes. We do not think the same ground should be used for the pen at less interval than three years.

We do not like the use of foldyards for lambing, but they are useful to have as reserves to fly to in case disease breaks out in the pen proper. The small pens made with thatched hurdles should not be massed too closely together, as it will only tend to spread any infection. Shepherds are rather fond of having their pens handy, and is quite natural, for it saves running about, and his duties are always arduous.

In spite of the free use of cake and other feeding materials cattle are not doing very well. Butchers complain that they are killing very badly, and are often nearly approaching 8d. per lb. when weighed and reckoned up. Butter and eggs keep steady in price, but hens will soon begin to lay and markets will soon be full. Fowls are still plentiful and fairly cheap, and will remain so until game is all consumed.

PERMANENT IMPROVEMENTS.—Every farmer should try to make some permanent improvements on his farm each year. We have visited, says the "American Agriculturist," many good farms, but never yet saw one that did not have some places where a little labour or a little money expended would not either make it more productive, more convenient, or more pleasant as a farm, and more valuable if offered for sale.

DAIRY UTENSILS.—In one of the Year Books of the United States Department of Agriculture is a thoughtful article by Mr. R. A. Pearson on the selection of dairy utensils, on methods and appliances for cleaning and sterilising dairy utensils, on the care and cleaning of dairy rooms or buildings, clothing of operators, and the thousand and one things to be considered in successful dairy work. A great point made by the author is the importance of selecting only such dairy utensils as can be easily cleaned. He says, "Other things being equal, the more accessible the inside surface of an article for dairy use, the more valuable it is. Any utensil having corners or parts which cannot be reached with water and a brush or cloth should be avoided. A vessel should be discarded if it has sharp, angular corners, unless they are absolutely necessary, for they require too much attention. All dairy utensils should be of hard material and have smooth surfaces. Wooden pails should never be used for holding milk, as in the surface of the wood there are numberless small pores and fissures. The joints and rims should be made smooth, and the cracks entirely filled with solder. Cheap tinware is put together so carelessly that the joints are often rough and uneven, and little projecting points of solder make it difficult to move the cleaning cloth along the seams. Pails and other circular tin vessels should have but one seam on the side; better ones are made without a seam. In order to facilitate the cleaning of the outside of utensils, they should be so finished that every part can be easily reached by water and cloth. The outside of tinware should be finished as smoothly as the inside, and all wood apparatus should be carefully finished on the outside, being made smooth and having as few projecting nuts, rods, and braces as possible."—("American Cultivator.")

BARR'S SEED GUIDE NOW READY (FREE).

BARR'S SEEDS

Of Finest Selected Strains AND TESTED GROWTH

THE BEST SEEDS IN THE WORLD for securing a supply of Vegetables "the year round," and for keeping the Flower Garden always gay, and with abundance of Flowers to cut for vases and bouquets; also Seeds of Plants for Greenhouse decoration summer and winter.

BARR'S SEED GUIDE contains a select List of the best Vegetables and the most beautiful Flowers for Garden and Greenhouse. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors, SENT FREE ON APPLICATION.

BARR'S .21/- COLLECTION OF VEGETABLE SEEDS contains a liberal assortment of the following useful Vegetables: Beans (Broad and French Beans), Beet, Borecole, Broccoli, Brussels Sprouts, Cabbage, Capsicum, Carrot, Cauliflower, Celery, Colewort, Corn Salad, Cucumber, Cress, Endive, Herbs, Leek, Lettuce, Melon, Mustard, Onions, Parsley, Parsnips, Peas, Radish, Salsify, Savoy Cabbage, Scorzoneria, Spinach, Tomato, Turnip, and Vegetable Marrow.

OTHER COLLECTIONS of BARR'S VEGETABLE SEEDS, 5/6, 7/6, 12/6, 42/-, 63/-, and 105/-.

These Collections sent carriage paid on receipt of remittance. Full particulars on application.

BARR'S CHOICE FLOWER SEEDS.—The "Seed Guide" contains a Select List of all the most beautiful Annuals and Perennials. Special Collections for all purposes, and many Sterling Novelties.

All Seeds sent Carriage Paid on receipt of remittance.

BARR & SONS,
12 & 13, King Street, Covent Garden, London.
Nurseries: LONG DITTON, SURREY.

LONDON FERN NURSERIES,

LOUGHBORO' JUNCTION, LONDON, S.W.—Stove and Greenhouse Ferns, large and small, in var., Aralias, Grevilleas, Cyperus, Ficus, Ericas, Palms, Dracenas, Aspidistras, Roses, Epacris, Solanums, Azaleas, Carnations, Cyclamen, Primulas, Marguerites, Crotons, &c. Trade, send for Wholesale List. Special Retail Catalogue, free.—J. E. SMITH.

PRIVET!

PRIVET for Hedges
PRIVET for Screens
PRIVET for Covert Planting
PRIVET for Ornamental Planting
PRIVET for Single Bushes for Garden Borders

THE BEST SORT FOR GENERAL USE.

3 to 4ft., 20/- 100; 4 to 5ft., 25/- 100; 6 to 7ft., bushy for screens, 18/- per doz., £6 per 100; 7 to 8ft., 24/- per doz., £8 10/- per 100.

SPECIMEN PRIVET.

For Single Bushes of PYRAMID shape, clipped, 4 to 5ft. high, 3 to 4ft. wide, 18/- doz., £6 10/- per 100; 5 to 6ft. high, 3½ to 4ft. wide, 24/- doz., £8 10/- per 100.

COMMON PRIVET for COVERT PLANTING
3 to 4ft., 4/- 100; 30/- 1000.

VARIEGATED GOLDEN PRIVET
AND OTHER ORNAMENTAL SORTS.

One good plant each of 12 kinds for 10/6.

See Catalogue Post Free for List of Sorts.

ECKFORD'S SPECIALITIES

ONLY GENUINE DIRECT FROM WEM
AWARDED 46 GOLD & SILVER MEDALS

SWEET PEAS!

The BIGGEST SUCCESS of all is ECKFORD'S GIANT SWEET PEAS. The PURITY and STAMINA of these Home Grown Stocks are so conserved by SPECIAL METHODS of CULTURE that the seeds are PHENOMENAL for UNRIVALLED STRENGTH and VITALITY, and with proper cultivation, give the HIGHEST POSSIBLE MAXIMA of results!

Prizes offered in 1900 alone exceed £40!

Collections from 1/6 upwards.

(See particulars in Catalogue.)

See beautiful plate of SWEET PEA NOVELTIES for 1900, sent gratis with each Catalogue.

CULINARY PEAS!

ECKFORD'S CULINARY PEAS are positively UNRIVALLED by any on the Market for FLAVOUR and CROPPING CAPACITY! ENORMOUS YIELDS under favourable conditions. Collections for 5 months continuous supply (See page 2 Catalogue.)

PURE VEGETABLE SEEDS!

Results from ALL QUARTERS prove that ECKFORD'S SEED, for PURITY, VIGOUR, and YIELD, are the CHEAPEST and BEST ever offered to the Public! Collection for 12 months supply, 12/6, 21/-, 42/-, 63/-, 105/-, all carriage paid. Other Collections, 2/9, 5/-, 7/6, post free.

CINERARIA (SILVER MEDAL STRAIN). Giant Flowers, splendid habit, unequalled!
PRIMULA SINENSIS. Unique Novelties and Grand Collection of named varieties
PANSY. World-famed strain of FANCY, SHOW, PEACOCK, and FLAKED VARIETIES!
VERBENA. RENOWNED RACE of EXCEPTIONAL MERIT!

ONION—NE PLUS ULTRA.

AWARD OF MERIT, R.H.S.

The Finest and Largest Onion for Exhibition Purposes.
2/6 PER PACKET.

Special Prizes for the best 12 Onions will be given at the Hemel Hempstead Horticultural Society's Show.

LEWIS DUNBAR, SEEDSMAN, HEMEL HEMPSTEAD

WEST'S PATENT GARDEN SPECIALITIES.

WEST'S PATENT

Vapourising Fumigator

Best and Cheapest, for being made of brass and zinc will last for years. The stove only requires a little spirits to saturate the asbestos, so may be used thousands of times without wick or further trouble than filling it. Price 6d. complete to vaporise up to 2500 cubic ft.

"WEST'S EXTRACT OF NICOTINE," is guaranteed pure Nicotine and is even cheaper than the compounds that are only chemical substitutes for Nicotine (compare prices), 7d. per air-tight sealed bottle of 1000 cubic ft.

"SUNPROOF" SHADING in 6d. lb. tins ready for use, to be mixed with cold water. Guaranteed to be perfect in all respects and the cheapest shading that can be made.

For particulars of West's patent "Ivory" Plant Labels, Soft Metal Tree Fasteners, S.M. Clips, Wall Nails, Plant Stake Grips, Plant Pot Cocks, Insecticides, Fertilisers, Canes, Sticks, and ALL GARDEN SUNDRIES of every description see Illustrated Catalogue, post free.

Samples free, postage for samples and goods extra. All goods made on the premises by C. E. West, so send direct to the Manufacturers.

Gratis, "Orchid Culture," 3rd Edition, postage 2d. Gives full particulars of the cultivation of Orchids.

BLOSSOM BUD FORMATION.

THE interesting communication on the {Rev. C. C. Ellison's garden at Bracebridge, near Lincoln (page 74), reminds me of days long gone by, when the garden and its trees were young. By the privilege of occasional visits to the garden thirty years ago, I learned some lessons from the practice and experiments of the active and earnest amateur. Active he appears to be still, it is a pleasure to learn, while his energy in fruit culture seems to have been lately re-invigorated.

If I were to say exactly what I used to think of Mr. Ellison in the old days it would be that he is energetic or nothing. In other words, if he undertook anything he did so with the full intention of succeeding. He appeared to devote his unquestionably strong brain and keen perceptive faculties to the solution of any particular problems that confronted him, and no research and labour were too great to deter him from arriving at the truth on whatever matter might be in question. If I were bound to name any one person who has impressed me more than any other, during a not short career, with a determination to "prove all things" on which doubts existed, that person would certainly be the founder, planter, and manager of the Manse garden at Bracebridge. I say "manager," for though Mr. Ellison has his gardener and assistants, and treats them after the manner of the thoroughbred English gentleman that he is, he still supervises all, and this in the happy way that makes it pleasurable to those whose duty it is to carry out his wishes.

In the description of Mr. Ellison's garden last week the interested visitor advised those who are not believers in pinching fruit trees to induce the formation of blossom buds to steer clear of Bracebridge Manse, or they would have the conceit taken out of them inside fifteen minutes. That I suspect is true, for it would be impossible to say how many thousands of blossom buds have been assisted to form there as the result of pinching the growths in the right way and at the proper time. Summer pruning, as ordinarily practised, is another matter, and has not the same effect. By systematically

No. 2679.—VOL. CII., OLD SERIES.

pinching the shoots of young trees root action is arrested, strong growth prevented, and a compact fruitful habit induced to fit the trees for certain positions in gardens. Even Peach and Morello Cherry trees can be made to produce clusters of blossom buds by pinching, and it would be strange indeed if Apples and Pears could not be brought into the same condition by similar means. The change is the simple effect of an arrestation of growth.

This arrestation can be brought about still more markedly in another way, with the result of a still greater and quicker increase in the number of blossom buds—namely, by checking the extension of the roots. This brings us more immediately to a case of “blossom bud formation.” This subject generally was discussed in the *Journal of Horticulture* some months ago, but left in a more or less nebulous state. Perhaps the narrative to follow will do something towards placing it on a concrete basis.

Once upon a time, which Mr. Ellison will recollect, the late Dr. Hogg visited his garden, but he may not be equally well aware that the present writer had a long and interesting discussion with the Doctor over the then young and promising trees. I know well, from experiments conducted for the purpose of acquiring information on the point, that a tree restricted in vigour by shoot pinching, and still more by root restriction, produced far more blossom in a given time over a given branch area than did a tree of the same variety of the same age and in the same kind of soil that was practically left to take its own course.

But though knowing that very well, there was a little matter that I did not know, and very much wanted to know. I have since found that there are men who really do know a great deal about gardening, but who do not yet know clearly what I was intent on extracting from the great pomologist. I tried to draw out of him what I wanted without betraying my own ignorance, but failed. At last, thinking if the opportunity was lost for enlightenment another of a like kind might never occur, courage born of despair came to the rescue, and the plunge was made in this way:—

“Doctor, I want to ask you a plain question on a definite point, but so simple it must be to you that I am afraid you will think me very ignorant, and I hardly like to proceed.”

“Oh, no,” was the reply; “I shall not think you ignorant, but should be inclined to think you were if you did not ask me anything you desired to know that I might be able to tell you.” That was something to be remembered, and the reply led me to ask scores of questions subsequently of whoever I thought could answer them. I was no longer afraid of seeming ignorant, and that has been a gain to me. But to proceed:—

“Well, Doctor, the simple question I want to ask is this: What is a blossom bud, and how is it formed?” A pause and penetrating look, then came this reply, slowly and thoughtfully:—

“You call that a simple question, do you? I call it a dual question, never before asked of me by a gardener. It is important, and I will answer according to my view of the matter.”

Then came the pronouncement, and it made the causes of certain effects clear that were before obscure.

“A blossom bud is an arrested and changed leaf or wood bud, and the embryo leaves are changed within it into floral organs, for all flowers are modifications of embryonic leaves, which if not arrested would develop into ordinary green leaves, such as you see around you.”

What a flood of light was thus thrown into a young inquiring mind. Then was seen more clearly than before why arrestation of vigour in the tree by pinching and root-pruning led to the increase in blossom buds.

Next followed an examination of buds. “Here,” I pointed out, “is one undoubtedly a blossom bud, and another unquestionably a leaf or wood bud; but what are these others? They appear to be neither the one nor the other; what will they become?”

“Oh,” was the rejoinder, “they are in the transition stage, and some may extend into growth, others be changed into blossom. Probably if this tree was nourished with liquid manure most of them would be forced into leaf-bearing shoots as they would if the branches were shortened; if that tree were taken up and replanted, thus stopping the sap pressure, the majority would be so far arrested as to bring about the change before mentioned, and the majority become blossom buds.”

All this was highly interesting, and now comes the sequel and the proof of the soundness of the Doctor’s “views.” I do not know whether the same subject was discussed between Mr. Ellison and his guest or not, but I do know that a number of young Pear trees of the same variety, all as like as trees could be in size, shape, stature, and

character, were growing side by side in the Manse garden. They were studded with buds in the transition stage—buds which no one could say with the least degree of certainty whether they would produce green leaves or floral leaves—blossom, when next summoned into activity. The owner of the trees, in accordance with his habit, decided to “prove” the influence of the arrestation of growth theory on the buds, by taking up and replanting every alternate tree. This was done in the autumn, and I saw the trees a week afterwards. The others were not disturbed.

Five months subsequently, or in the following April, I was invited to see the trees again, and was simply astounded. They afforded a sight and a lesson never to be forgotten. The transplanted trees, every one of them, were, so to say, “white” with blossom—studded most freely with trusses of flowers, not large, but in the aggregate decidedly imposing under the circumstances. A few of the unremoved trees had produced a cluster of flowers here and there, but several of them contained not a solitary truss, those buds that did not remain stationary, or apparently so, having extended into leaf-bearing shoots.

I am almost certain the facts were stated in the *Journal of Horticulture* at the time, but probably “buried” in an article. After a long and unavailing search for the record I some time ago wrote to Mr. Ellison on the subject of his experiment, and here is his reply:—

“Late in the sixties I grafted seventy-five Quince stocks with Beurré de Capiaumont, from which I raised seventy-three trees. Of these thirty-six were transplanted and thirty-five bore fruit in the following year. Of the thirty-seven not moved only one fruited. Seventy-two of these trees now form an avenue.”

No such direct and conclusive evidence on the acceleration of blossom buds by an arrestation of growth force, or reduction of sap pressure on certain buds, has, so far as I know, been published. It satisfies me at least that a tree does not, as some excellent men appear to think, give birth, so to say, to two distinct forms of buds—one predestined to produce shoots and green leaves, the other blossom and fruit, but only one kind is produced originally, and I strongly suspect the Doctor was right that a blossom bud is an arrested leaf or wood bud, nothing less and nothing more.

How far growth arrestation, either by shoot pinching or root shortening, is desirable for giving the most profitable results in fruit yielding, is not the question at issue, the facts stated having exclusive reference to blossom bud formation.—A LINCOLNSHIRE GARDENER.

CRYPTOMERIA JAPONICA.

THIS handsome Conifer is deserving of a place in any garden, being quick-growing, thoroughly hardy, and thriving in almost any kind of soil. In a young state especially it is a strong, vigorous-looking plant, and shows to advantage in practically any situation. A native of the mountains of China and Japan, it is largely cultivated in the latter country, especially for avenues, one in particular about fifty miles long being said to be planted almost entirely with this tree. In a wild state it forms a tree of pyramidal outline, 120 to 150 feet in height, but in this country the tallest specimens are probably not more than 50 feet high as yet.

Under cultivation it makes many spreading branches, which curve upwards at the ends, and which on old plants are bare for about half their length from the main stem. The leaves are closely set together on the branches, linear in shape, and sharply pointed. In cross section they show a somewhat four-sided outline, and are marked with two glaucous lines beneath. The cones are globular in form and prickly when ripe; and, though freely produced on comparatively young plants, do not always contain good seeds, which is probably due to bad weather during the time of fertilisation.

There are several varieties, of which the var. *elegans* (C. Veitchi) is undoubtedly the best, and which forms a remarkably handsome and useful garden plant, though it has been unfavourably reported on by some as rather tender, and instead of being a “thing of beauty” in the winter—when it is at its best—is said to be an eyesore. But it should always be remembered that Conifers—more especially those found outside of Europe—do not grow equally well in all places, a distance of a few miles making a great deal of difference in their habits, and no Conifer should be discarded until it has been thoroughly tested.

The plant in question was introduced from Japan in 1861, and has never been found in a wild state, probably being a sport originating under cultivation. It has a beautiful feathery appearance; linear, flattened leaves, much softer in texture than those of the type, and the secondary branches are short and slightly pendulous. The whole tree is of a bright green colour in the summer, but in winter it changes to a vivid bronzy crimson hue, the depth of colour, however, varying in different parts of the country, being much brighter in some places than in others.—C.

EPIDENDRUM WALLISIO-CILIARE SUPERBUM.

THOUGH the name given above is somewhat cumbersome, it has one distinct merit, inasmuch as it gives the parentage of the plant. It was shown at the Drill Hall on Tuesday, January 23rd, by Messrs. J. Veitch & Sons, Ltd., Royal Exotic Nursery, Chelsea, and received from the Orchid Committee of the Royal Horticultural Society a recommendation for a first-class certificate. The flower (fig. 20) is strikingly beautiful, and was probably as much admired as any Orchid in the hall on this occasion. The petals are of remarkable substance, and the colour is an intense deep yellow; the sepals are bright yellow. The splendid lip is about 1 inch across, and the colour is white on the outer portions, with showy bright purple in the centre. The spike carried five fully developed flowers.

PHALÆNOPSIS SCHILLERIANO-STUARTIANA.

On the same day as the *Epidendrum* was honoured, *Phalænopsis* made a wonderful display. The beauty and variety were alike charming, and the interest in the Orchid section would have been much less but for their presence. Two received special recognition from the Orchid Committee, and both were exhibited by Messrs. H. Low & Co., Bush Hill Park Nurseries. Of these we now illustrate *Phalænopsis Schilleriano-Stuartiana* (fig. 21), which received a first-class certificate. As a glance at the representation will prove it is of chastely delicate beauty. The broad petals are white with deep rose in the centre, as is the upper sepal. The lower sepals are white, with rose spots and suffusion, and the lip also is white with profuse rose spots.

DENDROBIUM WARDIANUM.

THE true type of *D. Wardianum* is a plant seldom seen nowadays, and though a very beautiful one, cannot compare with the handsome Orchid now sold under this name either for ease of culture or freedom of flowering. But ease of culture is here only a relative term, and though we can grow and flower our *Wardianums* finely while they last, they are not, unfortunately, by any means long lived under cultivation. What we know as *D. Wardianum* is a native of Burmah, and was discovered in the first place by Mr. Boxall, V.M.H., who sent it home to Messrs. Low & Co. about 1875.

Since then thousands of plants have been imported, and it is one of those Orchids that I should advise amateurs to purchase newly imported plants of in preference to any that have been under cultivation. The advantage is that these plants fresh from their native

FIG. 20.—EPIDENDRUM WALLISIO-CILIARE SUPERBUM.

habitat, produce very beautifully coloured flowers for the first season or so. Perhaps, finer flowers were never seen than those on plants exhibited at various centres last season on the imported stem, but probably many of these have not come up to the expectations of their owner this season.

But even in its poorer forms it is a chaste looking and lovely Orchid, and its popularity is not surprising. The original *D. Wardianum* is a much slenderer plant, that bears smaller flowers,

though these are perhaps even more brightly coloured. This is much like a small *D. Falconeri*, and was at first thought to be a variety of that species.

ODONTOGLOSSUM CRISPUM VIRGINALE.

From one of my correspondents comes a very fine flower of this chaste variety, broad petalled, prettily crisped on the margin, and altogether one of the finest of this type I have seen. Yet, although the plant he admits is weak, and the spike a large one, it has been allowed to remain on until the flowers commenced to fade. It is usually amateurs who do this kind of thing, many experienced growers removing the flowers immediately a really good form is noted on a newly imported plant for obvious reasons. It is a pity to farther weaken a valuable plant for the sake of seeing the flowers a week or so longer, and thereby ruin its chances for another year. *O. c. virginale* is not a particularly rare variety, but such good forms as this are uncommon.

DENDROBIUM CAPILLIPES.

This charming little plant has always been a favourite with me, and no matter who grows and flowers it well they are sure to be pleased with the masses of yellow blossoms so freely produced. Although one of the dwarfs of the genus it is as showy as many larger species,

FIG. 21.—PHALÆNOPSIS SCHILLERIANO-STUARTIANA.

and given a good firm hold in the lome of its adoption little trouble will be found in growing it. Of course such a plant will not do in a large pot with much compost about it, but in small pans or especially on Tree Fern stems it flourishes under the usual treatment accorded to *Dendrobiums*. A peculiarity is the very fine hair-like stems of the flowers from which the species takes its name.

ONCIDIUM HARRISONIANUM.

Many growers object to this species on the score of colour, which they do not consider as showy as many others, but the fine old gold tint in my opinion is as attractive as anything we have in dwarf Orchids. It likes a light and rather cool house, such as suits *Sophranitis*, and may be grown in small receptacles, giving a compost of equal parts of peat fibre and moss. It has glaucous leaves and pseudobulbs that distinguish it from any other kind, and is a native of Brazil.—H. R. R.

LONDON GARDENS OVER FIFTY YEARS.

No. 18.

WE have already remarked that though Osborn's was generally called the Fulham Nursery, the same name seems to have been sometimes given to another between Walham Green and Fulham. This was really at Percy Cross, a modern name which has much puzzled investigators. It is not likely to be altered now, but *Percy* could not have been its original spelling. Some argue it was "Purser's Cross," because a ship's purser was buried at the cross roads, who was a suicide or had committed a murder. Others uphold "Parson's Cross," asserting that hereabout stood a cross meant to guide people to the parsonage. We must leave the point doubtful. The Percy Cross Nursery was well known for many years, Mr. Dancer being a large grower of evergreens and fruit trees. In the time of Cromwell we read of one *Daunsar*, who was a benefactor to Fulham and Hammer-smith; apparently the Dancers were first farmers, then market gardeners, afterwards nurserymen. Besides this nursery the late Mr. Dancer had extensive grounds at Chiswick, near the gardens of the Royal Horticultural Society and the Duke of Devonshire's mansion.

Many went to Percy Cross Nursery to examine some remarkable specimens of *Salisburia adiantifolia*, planted early in the reign of George III., and other curious exotic trees. By an unfortunate accident a fire broke out in October, 1876, that entirely destroyed the storerooms and packing sheds, with a quantity of seeds in which Mr. Dancer then did a large business. About three years afterwards the growing stock of trees and shrubs was sold and the land cleared for building.

Ravensworth House, Percy Cross, has a memorable garden; commenced by Mr. Ord in 1756, it had some things visitors came far to see. Thus, there was in the kitchen garden a Moss Rose which had been repeatedly layered, till it covered a circumference of 45 feet. Amongst the trees was a Lombardy Poplar 10 feet in girth, and reckoned to be 120 feet high, also a *Juglans nigra* 60 feet high, raised from seed. The firm of J. Veitch & Sons have ground at Southfields, near Fulham, but they are not able to say whether it was formerly a part of the nursery of the famous Reach's, father and son. Reach, senior, is stated to have been an early grower of the *Auricula* and the *Chrysanthemum*; he had thirty-three children by two wives, yet reached the advanced age of ninety-nine! Some of the fields about Fulham used to have quite an aromatic fragrance in the summer season, as various herbs, Thyme, Basil, Sage, and Marjoram, were largely grown for Covent Garden Market.

Loudon, one of the very notable writers on horticulture belonging to the earlier years of this century, is not given to exaggeration generally, but he may have over-estimated the importance of the Vineyard Nursery at Hammersmith. He commences a brief account of it with the remark that it was certainly the first nursery in Britain, or, it might even be said, in the world, which we can scarcely admit, though allowing it occupied a place amongst a select few. Nor, even to this day, has it lost reputation, numerous as are its rivals of younger date, though the nursery does not cover the ground at Hammersmith it formerly did. What its original extent was seems to be uncertain now, but before it became a nursery the whole or a part of the land was occupied as a vineyard, and considerable quantities of wine were made there in favourable seasons.

The situation attracted the notice of two young Scotchmen, Kennedy and Lee, in their walks about the west of London, and they obtained the place to convert it to a nursery garden. (Here, again, we have an instance of the indebtedness of horticulturists to North Britain.) Lee came south to an engagement in the Chelsea Physic Garden under Miller, afterwards he became gardener to the Duke of Argyll at Whitton. About that time he got to know young Kennedy, then employed at Chiswick in Lord Bolton's establishment. The would-be wits of the reign of George I. called this Duke a "tree monger" because of the exertions he made to obtain varieties of trees from abroad. With James Lee it was the grand object of his life to obtain exotics from all attainable lands; also he had a hearty desire to promote and simplify the study of botany. He died in 1795, but it might truly be said his works follow him to the present time.

Probably it was about 130 years ago, soon after George III. became monarch, that the Royal Vineyard Nursery was established. In 1760 Lee published his important and useful "Introduction to Botany," designed to explain the Linnean system, illustrated, which passed through several editions. Though superseded now by the general adoption of De Candolle's natural system, it helped the progress of botany, and it made Lee acquainted with most of the first-class botanists of Europe. It seems likely this was written before he entered upon the responsibilities of business; later he issued a catalogue of exotics grown at his nursery. Lee was also an earnest student of shells, insects, and fossils, collecting all these. Many of them were drawn by his daughter Anne, besides various rare plants. The story of his having discovered the first *Fuchsia coccinea* brought to Britain, in a sailor's house at Wapping in 1788, has been often printed and often questioned, but I find that it is authenticated. Roses, too, were even in his time a specialty of the nursery, where he had the China varieties before anyone else. He lived till 1795, surviving Kennedy. An excellent portrait and sketch is in the *Journal* of January 25th, 1877.

After the decease of the founders their surviving sons carried on the nursery till 1818, when they dissolved partnership, and it became the sole property of James Lee, jun. He was followed by John Lee, who retired in 1877, having been actively engaged in the nursery for fifty-six years, and it entered upon a new era, being carried on by the fourth generation of the family, under the title of Charles Lee & Son. About the middle of this century the Royal Vineyard Nursery passed through a period of depression, from which it gradually recovered, and several new houses of improved structure were erected at Hammersmith by Mr. C. Lee, though the open ground has undergone diminution. Grapes still receive due attention on the spot which has so long been famous for them. Additional nurseries of some extent have been maintained successfully many years at Ealing, Feltham, and Isleworth.

If it be the fact that the first English Dahlias were planted at

Holland House, having been sent there in mistake for Artichokes, it is likely Lee was favoured with an early sight of them. They used to put the tubers in the driest road scrapings they could get, and kept them under glass, thinking the plants required warmth in our climate. It is impossible to enumerate the good things which have come from this nursery in recent years. Here was raised *Juniperus virginiana elegans* in 1869, a pleasing variety of Red Cedar. Notable also was the Weeping Black Bigarreau Cherry, with large fine flavoured fruit, which ripened there in 1878 for the first time in Britain.

Hammersmith has enormously increased its population during the half century, rising from 18,000 to 104,000. Hence it has spread largely towards Kensington and Fulham. Streets, factories, brick-fields, cemeteries now occupy much of the space that was garden ground in 1850. One calls to mind the names of Broadbent, Evans, Humphries, Matyear, Smith, and others, who used to send many tons of vegetables to market. Even yet, I believe, Mr. C. Bagley, one of a well-known race of gardeners, has land near the Packhorse and Talbot, a quaint old sign in the Hammersmith Road, reminding us of the time when much luggage went by packhorses, a spotted dog or talbot trotting in front.

But though market gardens and nurseries have diminished, it cannot be said that Fulham and Hammersmith are badly off for open spaces. 'Tis true old greens have sometimes become mere names—Starch and Walham Greens, for instance—but new gardens or recreation grounds have appeared. Ravenscourt Park, once renowned for its trees and flowers while a private residence, is a space of 32 acres, greatly frequented. It is one of several parks under the London County Council, which have a botanical garden containing collections of plants arranged in natural orders, and a guide is to be printed for the benefit of teachers or students. Eelbrook Common of 14 acres is now a park; then close to the river we have the Bishop's Park at Fulham of 12 acres, and adjacent thereto another space of 9 acres free to the public.—J. R. S. C.

SMALL DECORATIVE FERNS.

THOSE who have house furnishing with plant or table decoration know how useful small healthy Ferns are for filling up and to enhance the beauty of flowering plants used. Unfortunately the same species are in many cases repeatedly propagated, and one rather wearies of them. The pretty *Pteris serrulata*, in its many forms, is one of the best of all for the purpose; *Pteris tremula* is also excellent in every size, from the largest to the smallest.

This has led to their very common use, but there are many others not so frequently seen that would make a pleasing variety. Some of these, it is true, are by no means so easy to propagate as the well-known forms named above; and others, unfortunately, do not freely reproduce themselves from spores, but where there is a demand, and they are likely to be admired, the gardener may well stretch a point, and take a little trouble in the matter. The pretty *Cheilanthes elegans* ought to be much more grown, for, though it demands careful treatment, no difficulty will be found in freely propagating it by division. And here it may be well to note that this and similar habited Ferns look far prettier in small plants where the individual shape of each plant can be seen, than when these grow larger and thicker, and consequently become confused and crowded.

How charming, too, and how easily grown, are some of the *Pellæas* in a small state! We have *P. hastata* and *P. rotundifolia* that both thrive in quite a cool house, and the genus contains a large number of such. In the *Gymnogrammas* again there are several striking and easily grown forms. Those of the *schizophylla* section are often thought to be difficult to cultivate, but there was never a greater mistake. All they want is sufficient warmth and moisture with room, so that the tender fronds may not be rubbed. *G. s. gloriosa*, that beautiful variety so well known now in large and medium sized plants, is quite a gem in small pots just as the young fronds are creeping over the side, and the first young plantlets are appearing on their end. These latter, of course, afford the readiest means of propagation in this case.

Many of the *Adiantums* are largely grown already by private gardeners, but some of these even are much neglected. Any number, for instance, of the ordinary type of *A. capillus Veneris* may be seen; but how often do we see the prettily cut forms, such as *A. c. V. fissum*? Yet this, and many others, are as easily propagated and grown as the type, and with it would make a charming variety. Some of the broader leaved forms, too, as *A. c. V. rotundifolium* and *magnificum*, are hardly second to *A. Farleyense* for beauty. Raising these, and others, from spores would make a delightful hobby for anyone with the time to spare, for one never knows quite what is coming, and as the various types begin to develop they are wonderfully interesting.

Pteris scaberula would make a very pretty plant in a small state, but its propagation is so difficult without the best of convenience that

it is hardly to be recommended for the purpose in view. It may be divided, and so increased, but not to a small state, or it will be difficult to get the divisions to start. But it stands well, and so does *P. sagittæfolia*, a charming Fern, with foliage like that of our native Arrowhead, but smaller, and of a deeper green. Into culture there is hardly space to go here, and of course the list could be greatly lengthened; but I may say that with most of those enumerated the present is an excellent time to commence working up a stock.—H. RICHARDS.

FRUIT PRODUCTION.

WHEN at the last Drill Hall meeting of the R.H.S. Mr. Morris of Sandhurst somewhat oratorically invited the Fruit Committee to tell him where he could obtain the supplies of soft fruits he wished to have for drying according to the sample of Plums submitted, and thus put on to the market in competition with dried Californian and other fruit, he seemed to think it was only needful for him to ask and he would immediately receive. But those members of the Fruit Committee who know anything about fruit supplies could render to Mr. Morris no assistance. That gentleman said that dried fruit of the best quality, fitted to compete with imported fruit of similar character, must be retailed at 3½d. a lb., and that the price paid to the grower, inclusive of cost of transit to the place of manufacture, could not exceed 1d. a lb. That proposal certainly presented nothing of a tempting nature, and in no way offered better prices than were already obtainable in any market, whilst much below average prices.

GLUTS OF PLUMS.

That Plums should be the fruit most in request was natural, as these are stone fruits usually produced in the greatest abundance, and most cheaply, and are on the whole the best suited for drying. There seems to be a common belief prevailing that Plum crops are annually so heavy that gluts commonly result. It was said at the table that such crops as led to gluts did not occur oftener than once in seven years. If anyone embarking capital in Plum drying had to trust to getting fruit at a remunerative rate, only so seldom as that, the investment would prove to be a poor one indeed. Certainly we may get what may be described as heavy crops of Plums oftener, but as was also said, our market arrangements and means of transit have improved so much that good fruit, instead of being concentrated on to one market now finds its way all over the kingdom, and the heavy crop simply suffices to meet the nation's ordinary requirements for fresh fruit without leaving any surplus to be purchased cheaply for drying.

THE SURPLUS FRUIT.

The drying process may be said to be an admirable means of utilising all that surplus fruit of a country for which there is no other demand. That may be true of some continental, as well as of American countries, but it is not, and it is doubtful if it ever can be, true of Great Britain. Here we have to feed with fruit one of the densest and greatest populations of the globe, and that of a people essentially fruit-loving. The demand for all descriptions of fresh fruit in season is truly enormous, and for the best there is always a good sale. It is the inferior that hangs and becomes at any time a drug. Poor or inferior fruit never did pay to grow and never will.

SUPPLY AND DEMAND.

But outside of the requirements of the population for fresh fruit, there is also the huge demand existing for fruit for preserving as jam and jelly, and for bottling. We have seen of late, through police court prosecutions, how great are the quantities imported, as fresh as it well can be, from abroad for this purpose; and through these cases we are enabled to see how deficient are our own supplies to meet all existing demands. Were there introduced into the kingdom another method of preserving fruit in the form of drying, that abstracted some 100 tons of our present fruit supplies, the effect would be, of course, considerably enhanced market price for all fruit; but that would prove a rock on which fruit drying as an investment would eventually split, as such manufacture to be successful must be of purchased fruit at the lowest possible price, that it may contend in our own markets with the excellent samples of dried fruit from other countries.

HOW TO INCREASE THE YIELD.

After all, the question that needs consideration in relation to these matters is as to how far we can in a remunerative sense extend our present comparatively too small fruit supplies. Granted that those directions in which demands now exist will never fail, granted also that other forms of demand will arise, there is still the more important fact that the population increases at an enormous rate annually, and that such increase of necessity requires an increased supply. There is even more, because all experience points to the conclusion that beyond increase of population there is an increased demand being made for fruit in its various forms and phases by the existing population,

because the taste for fruit grows on them. There is no public taste in relation to food more healthy, more desirable, hence apart from the profitable aspects of fruit culture there are supporting it important hygienic ones that do not apply to every form of popular food.

FUTURE REQUIREMENTS.

Looking at these facts, then, the question naturally arises, What are we as a nation doing towards providing the supply of fruit for our people that not only now exists but is so rapidly growing? There is no subject in connection with economical horticulture so important as this is. It is a problem that needs to be solved. Very many persons would, perhaps, be startled to learn that there is little hope of meeting our future needs unless we put down annually some 40 to 50,000 acres of land with fruit. That may seem astonishing, but utilising an old exclamation, and remembering our vast nation of consumers may it not be said, What would its produce be amongst so many?

WORN-OUT ORCHARDS.

In our estimates of fruit areas we take little account of the considerable area of fruit land that is annually being converted to other purposes, or has become old and worthless. Practically there are many thousands of acres of land now containing fruit, and reckoned as such in Government returns, that, so far as the existing needs of a fruit supply are concerned, are absolutely worthless. Poor fruit is of no good to anyone; neither grower, dealer, nor consumer benefits by it. Apart from the poor prices it brings, so much of it wastes or decays that it is never remunerative. Generally good, clean, well grown, well finished fruit represents fully three times the value of poor fruit; yet it is not much more costly to grow, and is, as a rule, much less expensive to gather. If good fruit will not pay to grow poor fruit never will, hence the primary object of all who embark in fruit culture in any way must be to grow the best only, and to grow it well.

WHO WILL BE THE PLANTERS?

How are new breadths to be laid down? There seem to be two methods of getting this great necessity accomplished, and apparently only these. One is by the landowners themselves setting apart considerable areas of their estates and planting them under experienced judgment, and the other is by capitalists purchasing land or hiring it on long lease, and planting it. There is no prospect apparently, at least some previous experience in that direction does not seem hopeful, that fruit culture, however extensively conducted, will ever pay under the control of a limited liability company. The one great element of success when land is good and well situated, and then well planted, must be found in the managing head, and such experienced men are just now hard to find. A high authority said the other day, "Were I asked to supply a man capable of efficiently managing a large fruit farm, not only cultivating it well, but also of profitably marketing the crop, I could not do it, for I know of none such." Certainly of good gardeners we have plenty, but of managers of fruit farms we have very few.

WHAT WE REQUIRE.

Practically we sadly need a training school for such persons, and we have none. At present a pupil who wishes to become an expert in fruit culture and in marketing must pick up his information as best he can through a nursery, if he can get into a good one, and there rough it indeed; or he may get into an extensive market garden, and acquire some rough knowledge in a rather coarse and almost repellant way. But of real systematic knowledge and instruction he will gain little. Of the best descriptions of fruits, whether in kinds or varieties, of planting and treating the trees and bushes, of pruning and properly manuring them, of treating them for preservation from fungoid and insect pests, of best methods of gathering the fruits, or of grading and of packing finally for market he will learn nothing systematic. He may certainly obtain a good deal of knowledge of the hand to mouth order, but it has all the same been rough and tumble training.

BOOK LEARNING *versus* PRACTICAL WORK.

Now, rather than bother our heads as we yet do so much by cramming from books, to help to create a number of horticultural theorists, whose knowledge needs maturing with garden experience, what we really want is a great institution devoted almost absolutely to fruit culture from the market point of view, where young men could have a course of not less than three years training, specially to fit them to be wise fruit farm managers. Such an institution should have its 200 acres of fruit ground. It should have first-class practical instructors. It should teach students literally everything to be taught in relation to fruit culture, to fruit disposal, preserving, bottling, drying, and the entire round of methods of utilisation. This seems no doubt a big thing, but if not furnished whence is to come our future fruit growers? and without these of what use to plant fruit farms?—A. D.

NOTES ON MARÉCHAL NIEL.

WHEN grown under glass the pruning of this fine Rose is a matter of great importance, and cultivators are somewhat divided as to the better way. Many cut back the growths closely each year directly after the flowering. I have adopted this plan for a number of years with considerable success, but the sight of several plants created in some cases by close pruning, and in others by very moderate cutting, has rather modified my views in regard to the former practice.

The Rose trees in question fill a good sized span-roofed greenhouse, and are planted on each side, wires being fixed to train the growths near the glass. They were planted two years back, the object being the supply of blooms for sale. All the plants are budded on Briar stocks from cuttings, and are therefore dwarfs. The first season after planting a fair amount of growth was made, but the shoots were not strikingly vigorous, and in the spring of last year a few dozens of blooms were gathered of good colour and quality. After this came the test as to pruning, which is the principal object of these notes. The owner had been advised to cut hard back all the growths throughout the house. Not caring to undertake such a risk, as he thought, he used the knife in the determined way indicated on some half-dozen of the plants. With the rest he simply removed weakly growths and slightly shortened the longest rods.

That it was wise not to prune closely the present appearance of the plants or trees fully proves. The half-dozen were a considerable time in starting into new growth, and the result of the last summer's crop of shoots are a few short weakly-looking rods that cannot possibly bear high-class flowers a month or two hence. The majority, however, are magnificent in strength and health. The trees have furnished long clean rods that have run to the top of the house on both sides with leaves, large, deep green, and leathery. The "eyes" look plump, and nothing save bad management can now prevent an abundant harvest of fine blossoms.

Forcing is detrimental to Maréchal Niel Rose. At least the blooms lose in colour and substance when much fire heat is applied. A little may be necessary to keep away frost, because even in a cool greenhouse the growth buds seem anxious to move at the turn of the year. Little heat and little air are advisable; the latter, when it takes the form of cold draughts, is certain to bring mildew and green fly.

I shall watch the house of Roses seen recently for the future, because I have always considered Maréchal Niel on dwarfs as short lived. My favourite stock is the standard Briar. Budded on this one has noticed a less rampant growth; this is firm instead of gross. Soft wood favours canker. Such, at least, has appeared to me, so that when one hears of a comparatively large space being filled with the favoured Rose in a short space of time, one expects to hear in a season or two that the plant has died. I once had a specimen that bore 800 fine blooms two years after planting, and after the crop had been gathered the tree died in some unaccountable way.

Near the spot where I write is a very fine specimen trained to the south-east side of a dwelling house. The position is high, and the soil dry and of a sandy nature. This tree is about five years old, and last year bore really grand blossoms. The leaves now present a most healthy picture, the frost we have had not being severe enough to harm them. There are many spots in gardens where this beautiful Rose would do well if tried. When once a favourable position has been obtained it is glorious as a climber, and gives practically no trouble beyond nailing in the shoots. Little pruning in the case of outside specimens is required, and although it is not a continuous flowering variety, I fancy most persons are more delighted with one perfect blossom of Maréchal Niel than a handful of almost any other Rose that is cultivated.—H. S.

HOW FERTILISERS AFFECT POTATOES.—Three years' test at the Virginia experimental station seems to warrant the conclusion that Potatoes grown without fertilisers contain the greatest amount of dry matter. The addition of fertiliser tends to diminish the dry matter in proportion to the amount applied. Potatoes grown with sulphate of potash contain more dry matter than where muriate was used. The ash, says an American contemporary, did not appear to be affected to any appreciable extent, and the same is true of starch. Neither the kind nor the amount of fertiliser seemed to have any effect upon the percentage of nitrogen, phosphoric acid, and potash, but the percentage of chlorine was considerably higher when muriate of potash was used and increased with the amount applied.

SPRAYING FRUIT TREES WITH SULPHATE OF COPPER.

ON page 6 "Y. B. A. Z." says he proposes to give his Plum and Pear trees a double syringing of sulphate of copper (1 lb. to 25 gallons of water) whilst resting, and again when the buds begin to swell, in order to prevent the attacks of brown rot fungus, *Monilia fructigena*; also in the hope that the Pear midge, *Diplosis pyrivora*, may find the treatment disagreeable.

May I suggest to your esteemed correspondent the omission of the second dressing, "when the buds begin to swell," on account of its rather dangerous nature to those buds which may be sufficiently open in the scales to allow the solution to enter. The solution of copper sulphate, at a strength of 1 part in 250 parts water, 1 lb. to 25 gallons, acts disastrously on developing as well as developed growths, whether leafy or floral, the strength quoted being only permissible before any growth has developed.

If the solution is used at all after the buds start, it should be at a strength of 1 part sulphate of copper in 8000 parts water, or 1 lb. to 800 gallons; if Paris green be added for the Pear midge and similar "gentry," 1 part in 12½ parts of the copper sulphate solution for Plum, and 1 part in 20 parts for Apple and Pear trees; or 1 lb. Paris green to 200 gallons of copper sulphate solution for Plum, and 1 lb. Paris green to 320 gallons of sulphate of copper solution for Apple and Pear trees. There would then be a chance of killing two birds with one stone—the parasitic fungi, and the predatory insects or their larvæ.

But in order to grapple successfully with parasites and predatory insects we must understand something of their life histories, and of the two pests named by our friend, that of the brown rot fungus, *Monilia fructigena*, has not been completely worked out. All we know is the conidial condition and the sclerotia stage, the perfect or ascophore form being unknown, or at least imperfectly determined. The fungus, however, passes the winter in the sclerotia stage, known as *Sclerotinia fructigena*, consisting of small, black, wrinkled bodies, mostly concentrically arranged on affected fruits, especially fine, on Doyenné du Comice Pears, and from these spring short flask-shaped branches or hyphæ, bearing globose conidia or spores, which give rise to the disease anew.

The diseased fruits bear on their affected surfaces, sometimes in the core cavity, dense tomentose tufts, often growing in circles, white, then dingy ochraceous red. This is *Monilia fructigena*—hyphæ branched bearing elliptical spores, usually in chains, and in this matrix the small black bodies, *Sclerotinia fructigena* form, practically wet, drought, and frost proof. I do not exactly, but very nearly, know they are also poison proof, for the way the simple solution of copper sulphate acts is by abiding on the sclerotia, and preventing the growth from these of young mycelium, consequently the development of spores is prevented.

It is well to remember that the brown rot fungus also attacks the leaves, though less frequently than the fruits, hence the winter spraying may be useful in acting upon any sclerotia on the trees or ground, otherwise the spraying whilst the trees and fungus are dormant can have little effect where cleanly culture—the destruction of all diseased fruits and leaves—is practised, for it is the sclerotia that constitutes the danger of infection.

I cannot grasp the idea, much less the fact of summer spores surviving the winter, except on living tissues in hyphæ form, or on diseased fruits in the fruit room, and after being thrown on the rubbish heap, to produce conidia or summer spores in the spring. I think no one better than "Y. B. A. Z." will fail to recognise the importance of burning all affected fruits as early as possible, then winter spray the trees with simple solution of sulphate of copper, though, as before stated, it may not do much, if any good, but it certainly will kill any lingering *Monilia fructigena* spores, and there is no harm in the application.

For the summer treatment I should depend on dilute Bordeaux mixture, never using it stronger than one part of copper sulphate to 125 parts water, and of course one part lime. This 1 lb. copper sulphate and 1 lb. freshly burned lime in 12½ gallons of water is quite strong enough for use on Apple, Cherry, Pear, and Plum trees; and with an ounce of Paris green paste added to the mixture for Plum trees, or three-quarter ounce for Apple and Pear trees, is as good as anything for fungi and biting insects. Spray first before the blossoms open, then as soon as the fruit is well formed spray again, and repeat the application twice later at intervals of a fortnight if wet, or three weeks if dry weather prevail.

For the Pear midge I should dress the ground with a mixture of kainit and bone superphosphate in equal parts, 7 lbs. per rod, and point in, and in spring when growth begins use 1½ lb., crushed fine, nitrate of soda per rod, and leave for the rains to wash in. Another thing, just when the buds commence swelling spray the trees with tar water—half a pound of gas tar boiled for half an hour in 2 gallons of water, and then dilute to 50 gallons. It may deter the Pear midge from visiting the trees from neighbouring orchards or gardens, for with the application of kainit and superphosphate now, and the nitrate of soda later, I do not expect any will rise from "Y. B. A. Z.'s" grounds if the mixture extend quite a yard beyond the spread of the branches of infested trees.—G. ABBEY.

THE SWEET PEA CONFERENCE.

As an admirer for many years of Sweet Peas, and knowing well their utility as a garden flower, I feel peculiar interest in the suggested Show and Conference to be held. As a cultivator and a keen observer of the varieties, and, I might say, the multitude of names that is so fast growing, I welcome the proposed Conference as a means of classification of those sorts which are too much alike to have any other but ill effect upon those we are all wishful to assist—beginners. It cannot be denied that names are increasing faster than are the actual varieties; at least, if some are not identical they much too nearly resemble each other to be either useful or necessary. A thorough system of classification should do much to make plain which are desirable varieties to grow.

An exhibition confined to this flower only will show us the best methods of staging them for effect. At the present time there are many styles of arrangement which are hardly worthy of emulation. It is the best, and the best only, that we require to see.—E. MOLYNEUX.

VINES IN THE OPEN.

In the editorial paragraph on page 54, in which an article from the "Globe" is quoted, there is a reference to the culture of Grape Vines on the walls and gables of cottages and farmhouses in the south of England. I should like to add that this phase of Vine culture is by no means an uninteresting feature in some of the rural districts of Kent, and though profit is probably not considered, there is something quaint and homely about the Grape Vine clustering over the door of a rustic dwelling, and apparently doing its best to obscure the windows. Only last September I passed a cottage, the front of which was entirely furnished with a Grape Vine, on which numbers of ripe bunches were hanging.

The grower evidently knew something of the rudiments of Vine culture, for I observed that the bunches had been thinned, and the black berries were of fair size and colour. The laterals had also been stopped in the orthodox manner; and closer examination disclosed the fact that a number of canes had been trained perpendicularly up the wall, and the spurs pruned closely. Treated in this way, and with the advantages of a very favourable summer, the fruit was of a highly creditable character, and to me it was an illustration of what the Grape Vine is capable of doing, even out of doors in this country, under certain conditions. I was not able to learn from the grower the name of the variety. It was there when he took the house, in a semi-wild state, and that was all he knew.

Even in wild unrestrained luxuriance Vines on house walls have something attractive about them, and I have often seen them heavily cropped with small crowded berries, but where cultural skill is brought to bear on them, and the season is favourable, useful Grapes can be grown in suitable situations in the southern counties. This does not alter the fact that to attempt to grow Vines outdoors as a commercial enterprise would only be courting failure.—KENTISH MAN.

HORTICULTURAL EXAMINATIONS.

THE paper recently read by Mr. George Gordon at the Horticultural Club on this subject is full of interest, and certainly strikes the keynote to another tune, which, by the re-arrangement of a few chords, will be more acceptable and harmonious to the gardening craft. For over twenty years I have been intimately connected, either as a candidate or examiner, with practical gardening, and also with examinations of various kinds, and since the inauguration of the R.H.S. examinations I have been preparing young gardeners as candidates. The ideal of an examination should be to test the candidate's knowledge of the subject, and the more practical the test the more satisfactory the results to everyone concerned. The answers to a few questions form no criterion of knowledge and ability, therefore it is evident some other system will have to be introduced if the confidence of gardeners is to be obtained and maintained, and if a certificate is to be of any real value to the apprentice or journeyman.

Mr. Gordon's suggestion of an examination scheme is worthy of serious consideration, for when I have scanned the results of the R.H.S. exams, and found thoroughly practical men with many years' experience in the third class, whilst boys and girls in their teens, without any practical experience worth mentioning, are in the second and first class, I have been constrained to think it was time the examinations should be placed and worked on a different system, so as to really meet the requirements of gardeners; but by no means should they be allowed to fall through.—S. H.

It must be over thirty-five years since I had to pass examinations, though I had a good many to go through even in those days. Perhaps the rising generation is more gifted and requires sterner trials, but if those eight questions on page 79 of the Journal are a fair sample of the sixteen in a recent horticultural examination, I should call it a very stiff paper.

One or two of the questions may be fairly easy, but to answer, in a really satisfactory way, eight such in two and a half hours,

seems to me a very hard task. Five or six years ago I essayed to answer one of those questions, and did so, though not quite to my satisfaction. It took me about six months. The immense amount of condensation required could only be learnt by "cramming," at least I should think so, but I have no personal experience of that process. Condensation is a literary art, requiring time, not only in the learning, but also in the carrying out. Demosthenes, the great orator, being once longer than usual in meditation before one of his speeches, was asked it is said, the reason of it. "I am thinking," he replied, "how I can shorten what I have to say to the Athenians."

To "rattle away" is comparatively easy if you know your subject, but to "boil it down" must take time. I am sincerely thankful no such two and a half hours task falls now to my lot.—W. R. RAILLUM.

APPLES AND IRON PIPES SPLITTING BY FROST.

My experience is precisely the same as that of "W. N.," page 71. I have had Apples frozen quite hard in a loft in which fruit was kept; Onions also, and both when moved about rattled like stones. When the thaw came numbers of the Apples split, in fact most of them were spoiled. The frost was very severe, the thermometer registering below zero in the open. The Onions were not injured. The Apples were not burst by the "thaw," but by the frost. There is no expansion of water when the ice melts, but slightly the reverse, and the fluid then escapes through the fissures produced, it may be, several days, or, as in the great frost of 1895, weeks before, though of course there could be no trickling so long as the water remained solid.

That water "swells" when warmed many gardeners know by its rising in and sometimes overflowing from the boiler feed cisterns when these are not as they ought to be, the warmer molecules of the water rising to the surface, but just because of the circulation and upward rise in the feed cistern the pipes cannot burst. But they can and do when circulation ceases and the water with which they are filled is changed into ice.

Some years ago a gardener was forbidden to use any fuel to exclude frost from a range of Peach houses during the winter. He was not told to empty the pipes, and a severe and prolonged frost occurring, hundreds of feet in length were raised and split. The mischief was not done at the time of the thaw, as has been said occurs, but by the tremendous pressure consequent on the expansion of the water during its conversion into ice.—AN OLD GARDENER.

I WILL be serious; and, indeed, my humour did not seek to dispute the patent fact that heat expands water. But I protest against Mr. Richards persisting in the error of his ways and against his endeavour to get out of a tight place by saying he was dealing with water only as a liquid. Now Mr. Richards applies the theory of heat expansion to demonstrate the possibility of thaw bursting pipes; he, perhaps, does not know that water is at its coldest when thawing—colder even than ice. How can any theory of heat expansion account for a substance bursting its containing vessel at its coldest? Melting ice absorbs heat, and thawing water is therefore below freezing point. If this were not so, the whole frozen surface of a lake would change into water immediately the thermometer stood above freezing point. Mr. Richards would then find skating an even more dangerous amusement than freezing bottles—and not so slow.

Perhaps the phenomenon of thaw bursting pipes observed by Mr. Richards may be explained by the fact that ice does not leak, and the fracture caused by the ice is not noticed until the thaw, when the escaping water draws attention to the breakage. At the same time I quite admit the possibility of heat applied to frozen pipes bursting them, not owing to the expansion of the water, but to the unequal expansion of the pipe, as hot water cracks a cold tumbler.—RET RAILLUM.

DECADENCE IN WALL TREES.

"A. N. O.," on page 52, is a little severe upon some people; scarcely gardeners one thinks. What a "modern go-ahead" is seems somewhat incomprehensible, but that he is a man in a hurry can readily be understood, and, of course, with trees "3 or 4 feet above the wall," he is not a gardener. That he may be called so is another matter and another tale. A gardener can scarcely listen to the wail of wall tree woe without feeling that it is a slur on his vocation. Still, the fact remains that neglected trees are not only frequently seen, but in the suburbs of a big city this neglect amounts to an epidemic. The cause is not far to seek, but it would take longer to detail than time and space now permit. It can, however, readily be given if desired; but so far as a cure is concerned, *cui bono?* "A. N. O." means well, doubtless; but he might as well have addressed his remarks to Queen Victoria as to the "modern go-ahead," who, we dare affirm, reads not the *Journal of Horticulture*—alas! Would that he could follow "A. N. O.," whose pen runs on "from grave to gay, from lively to severe," for, although the modern go-ahead might never be a gardener he would, at least, have received an elementary lesson in gardening, as well as the sound castigation he so richly deserves to enforce it, from "A. N. O."—A. N. OLDHEAD.

Recent Weather in London.—At last we have had one touch of real winter. This was on Sunday morning, when we awoke to find everything enveloped in a mantle of snow. It did not remain long, however, but was succeeded in the afternoon and evening by a cold driving rain. Monday was dry until evening, when there was a slight drizzle, but the wind continued very cold, and the same conditions prevailed on Tuesday. A slight drizzle fell on Wednesday morning.

Weather in the North.—For a week we have had rain almost every day or night, with frequent high winds from the west. The 23rd was fine for good part of the day, and there were a few glimpses of sunshine on the 25th. On Saturday morning heavy showers of sleet and snow were followed by a fairly good day. Sunday morning brought fully an inch of snow, and 8° of frost were registered during the night. All the surrounding hills have been thickly covered with snow during the week, and on Monday the low grounds still were white and the day good.—B. D., *S. Perthshire*.

Coleus thyrsoides.—In several of the houses at Kew groups of this charming plant are to be seen, and in each place it appears to attract more attention than any of its neighbours. Seeds of it were received from British Central Africa a few years ago, and this is the third time it has flowered at Kew. Judging from its behaviour up to the present time, it is likely to prove one of the best winter-flowering additions of recent years to the warm greenhouse. The leaves are very similar in size and shape to those of the ordinary garden *Coleus*, but are not variegated. The flowers are borne in terminal inflorescences, often 6 inches long, a very large number of flowers going to form each head. They are bright blue in colour, and make a most effective display, especially if shown against a dark background of foliage. The cultivation is as simple as that of the ordinary garden forms. Cuttings inserted in spring and stopped frequently make large plants in 7 or 8-inch pots by autumn. A cool house or frame is all that is necessary during summer, or the plants may even be plunged outside. After they are housed for winter a minimum temperature of 45° should be given, raising it 5° when the flower spikes begin to show. It may be had in flower from Christmas onwards for a month or six weeks.—W. D.

Warranty of Seeds.—There seemed to me in the decision given by Mr. Justice Channell in the case reported on page 49 last week to be more that was legal than was moral. Until I read the report of the case I could not conceive that any honourable firm would shelter themselves behind such a defence as was made, that the vendors gave no warranty and would be responsible for none. Surely it is but fair to the purchaser that he should have an express guarantee that the seeds ordered by him are sent in strict accordance with his order, and it would be only just on the part of the vendor to give such warranty, and be responsible for it. In the face of such a decision a grower may order Melon seed and get Cucumber, or Tomato and get *Solanum capsicastrum*, or Cauliflower and get Turnip, or Ailsa Craig Onion and get James' Keeping. Indeed, the changes might be rung on all sorts of things with the same result, according to Mr. Justice Channell's decision, that so long as the vendor declares he gives no warranty then he is safe from claims for damages. One naturally wonders whether this form of morality, or lack of it, characterises the whole seed trade. The case was in one of its phases rendered absurd by the defendant setting up a counter claim for £60 as the product of the loss of 3s. worth of seed. That was of course ridiculous. But there may have been material injury done through the stupid blunder of the plaintiffs to the defendant, if he was, as seemed to be the case, in the habit of raising thousands of Celery plants of, as the name of the variety shows, one of the finest and most widely grown of Celeries in the north, and he may have been expected to compensate his numerous customers for the losses they had sustained in not having their favourite Celery to compete with at their local shows, also in loss of reputation because of the trouble thus created with his clients.—A. D. [Cannot the purchaser be said to have expressly waived his right to implied warranty by ordering from the seedsman's form?—ED.]

Gardening Appointment.—Mr. James Mitchell, head gardener at Glenstal Castle, Murroe, co. Limerick, and many years general foreman at Castleborough, Enniscorthy, has been appointed head gardener to C. M. Doyne, Esq., Wells, Gorey, co. Wexford, in succession to Mr. Dennett.

Massachusetts Horticultural Society.—We have just received a copy of the complete schedule of the exhibitions to be held under the auspices of this Society during the year. There are about twenty-four shows distributed throughout the twelve months, so that it is practically impossible for any crop to miss having a place at the period when it is in the best condition. Amongst the total of 800 classes the sum of \$150 dollars is distributed. Such a strong society should be a power for good over the radius that its members extend. The Secretary is Mr. Robert Manning.

Honouring the Famous.—Every year the practice of naming new varieties of flowers after persons who happen to be men of the hour is becoming more common. The latest additions are *Cypripedium* Sir Redvers Buller, and Generals Roberts and French in the way of Primulas, and as famous soldiers seem to be the order standing first at present, raisers of fresh varieties should have no difficulty about naming their prizes if they take South Africa as a field from which to get the titles. Lord Kitchener was, I think, honoured in this way at the end of the Soudan campaign, but there is plenty of material at hand just now, when we think of Methuen, Gatacre, White, Baden-Powell, and a host of other heroes. Raisers are surely not at a loss now for names for fresh introductions, and perhaps the latest in Chrysanthemums will be "The Absent-Minded Beggar."—V. T.

Cardiff Societies.—The annual general meeting of the Cardiff and County Horticultural Society was held at the Town Hall on Thursday last, when a large number of the Committee and subscribers attended. The report and balance sheet for the past year were passed, and the accounts are considered very satisfactory. The following officers were appointed:—President, the Worshipful the Mayor (Councillor S. A. Brain); Chairman of Committee, Mr. S. Medhurst; Vice-Chairman, Mr. John Grimes; and Secretary, Mr. H. Gillett. The dates of the annual show were fixed for July 18th and 19th, and the schedule was arranged and will be issued forthwith. The Cardiff and District Chrysanthemum Society has fixed November 7th and 8th for the next annual show, and at the general meeting on Friday last the following officers were appointed:—Mr. John Howe, Chairman of Committee; Mr. George Shewring, Vice-Chairman; and Mr. H. Gillett, Secretary. Regret was expressed that the late Chairman, Mr. F. G. Treseder, had to resign through pressure of business, and a hearty vote of thanks was passed by the Society for the able manner in which he had filled the office of Chairman for the past three years.

Birmingham Gardeners' Association.—The annual business meeting was held on the 22nd inst., Mr. W. B. Latham presiding in the unavoidable absence of the President of the Society, Professor W. Hillhouse, Mason's College. The report shows that favourable work was done, and that excellent lectures and papers were given by experts; also an increase in the membership by horticulturists, and likewise a very pronounced increase of readers of the numerous and valuable books of the library. Office-bearers were re-elected, and resulted as follows:—President, Professor Hillhouse; Vice-President, Mr. J. W. Oliver, science teacher, Technical School, Birmingham; Chairman, Mr. W. B. Latham; Vice-Chairman, Mr. Walter Jones; Librarian, Mr. W. Gardiner; Treasurer, Mr. W. Spinks; Secretary, Mr. W. L. Deedman; Auditors, Messrs. Redfern and W. Dodd; Committee, Messrs. John Pope, C. H. Herbert, C. R. Bick, W. B. Childs, W. Hiron, T. Mumford, Alfred Cryer, G. Pressly, G. Stacey, H. A. Burberry, and E. J. Mustin. At the same meeting, in response to the prizes offered by the Committee for three Cyclamens in pots, Mr. A. Cryer, gardener to J. A. Kenrick, Esq., Berrow Court, Edgbaston, was awarded the first prize for very fine examples; the second prize falling to Mr. Dedicott, gardener to Alfred Wiggin, Esq., Northfield; the third to Mr. E. J. Mustin, Moseley; and an extra prize to Mr. J. Maldrem, Northfield, all with worthy exhibits. Mr. Mustin also brought a few cut flowers of late Chrysanthemums; and Mr. G. Stacey an excellent dish of Seakale, well-kept Apples, and a fine dish of Industry Potatoes. The meeting closed with the decision to hold the annual tea reunion of the members and lady friends either on the 14th or 21st of February, subject to arrangement.

Hessle Gardeners' Society.—A fortnightly meeting of the above Society was held in the parish schoolroom on January 23rd, there being a record attendance; Mr. Mason occupied the chair. The essayist for the evening was Mr. Judson from the East Park, Hull. The subject, which was Chrysanthemums, proved to be one of the most popular ones of the session, and was thoroughly practical and instructive in every detail. The essayist made it clearly understood that anyone who wishes to excel in the production of these popular flowers must pay strict attention to every detail of their culture at all seasons. An interesting and instructive discussion followed. Votes of thanks to the essayist and Chairman terminated the meeting.—J. F. D., *Yorks.*

Reading Gardeners' Association.—The members of the above Association assembled in force on the occasion of the annual tea and smoking concert, which took place on Monday evening last in the Abbey Hall, kindly lent by Messrs. Sutton & Sons. The President, Mr. C. B. Stevens, presided at the tea, which commenced at 6.30, the company including Mr. Leonard Sutton and Mr. M. H. F. Sutton. The tables and hall presented a bright and pleasing appearance, having been decorated under the supervision of Mr. Macdonald with foliage and flowering plants sent by Mr. J. Woolford, The Gardens, East Thorpe, and Messrs. Sutton & Sons. During the tea the Chairman gave the toast of "The Queen," referring to the great trials Her Majesty was passing through, and spoke of the kindness and sympathy she was showing to the friends of our gallant soldiers fighting in South Africa. Subsequently he presented to the winners the prizes offered in the essay competition. At eight o'clock the smoking concert commenced, presided over by Mr. Leonard Sutton, and it was without doubt the best and most varied ever held at these annual gatherings.

Liverpool Horticultural Association.—There was a fair attendance of members on the occasion of the annual general meeting, Mr. Thomas Foster presiding. There had been a small loss on the year's working, but the Association have in hand a balance of £92 2s. 1d., which, according to the many demands at present on the public, was considered satisfactory. Even when low in funds members have never forgotten the charitable institutions, and this year grants of 3 and 2 guineas were made respectively to the Gardeners' Royal Benevolent Institution and the Royal Gardeners' Orphan Fund. The election of Committee followed, the new members being Messrs. E. Bridge, J. Rimmer, J. Bracegirdle, John Stoney, T. Carling and E. Finch. The Lord Mayor (Louis S. Cohen, Esq.) was elected President, and it is to be hoped that the Committee will endeavour to secure his presence at the opening of the forthcoming spring show to be held in St. George's Hall. Mr. Harold Sadler was unanimously elected Secretary, many gentlemen present testifying to his geniality and business-like capacity. Mr. W. Fletcher Rogers and Mr. G. Blackmore were respectively appointed Hon. Treasurer and Sub-Treasurer. Spring and autumn shows were agreed to. Mr. Stoney proposed a hearty vote of thanks to Mr. Foster for presiding, and a most pleasant and successful annual meeting was brought to a close.—R. P. R.

Bristol Gardeners' Association.—The fortnightly meeting was held at St. John's Parish Room, Redland, on Thursday, 25th inst. Mr. C. Lock, presided over a large attendance. The meeting was especially interesting by reason of a paper read by a member from the Cardiff Gardeners' Association, Mr. J. Graham. Under the title, "Gleanings from a Horticultural Class," Mr. Graham dealt with a variety of subjects, all of great importance to gardeners, such as soil and its constituents, bacteria, thermometers, dew and rain, laying out pleasure grounds, rockery formation, draining of land, and plant diseases. He dealt with the subjects in a vigorous and able manner, giving much useful information. Mr. Graham strongly urged the formation of botany classes in connection with gardeners' associations, claiming that a knowledge of theory was a great help in practical work, and pleaded for more sympathy between head gardeners and their assistants, being cordially thanked for his attendance and paper. Prizes for a Pitcher Plant were awarded—first, Mr. White, second, Mr. Bannister, and a certificate of merit to Mr. Ross for a *Primula sinensis*. An exhibit of great interest was provided by Mr. Graham, who showed over fifty dried specimens of British plants, which attracted much attention. A motion of sympathy with the relatives of the late Canon Ansley was passed. The late Canon was a Vice-President of the Association during his residence at Redland, and took a keen interest in the work from the time of its formation.

The Imperial Yeomanry.—Messrs. Boulton & Paul, who had given a frame house for a hospital ward, have now added a similar house, with kitchens and offices complete, for the use of Mr. A. Fripp, the hospital surgeon. The ward house will contain thirty-five beds.

"Lawns."—Messrs. Sutton & Sons have sent us a copy in pamphlet form of their useful work on the formation of lawns of various sizes and for different purposes—handy for reference by gardeners; we have also received a thoroughly well-bound copy of the same work, clearly printed on stout paper, and enriched with photographic illustrations—worthy of a place on the drawing-room table. The instructions on preparing the ground for new, and improving old lawns, are concise and to the point—so clear, in fact, that they cannot very well be misunderstood, and as the information is the result of great experience, it possesses the great merit of trustworthiness.

Chemical Manures.—This was the subject of a lecture delivered by Mr. F. W. E. Shrivell at the fortnightly meeting of the Reading Gardeners' Association, on Monday evening last. The Lecturer, in an interesting manner, laid before the members the results of the various experiments carried out at Toubridge during the past five years with chemical manures on vegetables and fruit crops. An interesting discussion followed. On the proposition of the Chairman (Mr. Fry) a hearty vote of thanks was accorded to Mr. Shrivell for his lecture, and to Mr. F. Lever, The Gardens, Hillside, for staging an exceedingly well-flowered plant of *Cœlogyne cristata*. Six new members were elected.

Apple Bramley's Seedling.—The good qualities of this variety are yearly getting better known, and any Apple of its class that keeps hard, firm, and full of juice at this time of year is welcome in the kitchen, while those whose tastes are inclined to a brisk flavour will be sure to like it for eating. Its free growing qualities and fruitfulness are also well known, and many of the fruits take on a fine colour after being stored, an attribute not common to really good varieties. In sending us fruits of it, Mr. Henry Merryweather, who sent it out, remarks on this last point, and really some of the fruits are as finely coloured as a Worcester Pearmain in October, and as solid and heavy as the day they are gathered. They evidently know how to keep fruit at Southwell.—C. HALL.

Notes from Ireland.—The weather in the Irish metropolis is anything but gay; rain is frequent, although we have had a sprinkling of fine days. Cyclamens and Primulas in variety add a charm to an otherwise dull outlook. At a recent meeting of the Royal Horticultural Society of Ireland the large silver medal given by the trustees of the Williams' Memorial bequest was awarded to Mr. Andrew Porter, gardener to Lord Ashtown, Woodlawn, Galway, with a total of fourteen first prizes, exclusive of seconds or any lesser awards. It was closely contested, as Mr. T. Byrne, gardener to George Drimmie, Esq., Bellevue, Booterstown, had a total of thirteen. In a recent issue I alluded to J. H. Dudgeon, Esq.'s, orangery, remarking on the non-edible fruits; I have since been sent a sample which completely reverses my former opinion, as the fruits are fine and juicy.—A. O'NEILL.

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet.

Mild spring-like weather has prevailed during the past week with small quantities of rain on five days.

IRIS SAARI NAZARENSIS.

THE species *Iris Saari*, which is a near relative of the *Iris iberica*, first came into notice during the year 1876. It differs from its congeners in the respect, that the standards are more incurved and the falls are ascending oblong and not obovate. Otherwise in its origin and its habit it resembles *I. iberica*, and the same treatment suffices for both. The district of the Caucasus between Armenia and Persia is

sun. They will thrive better there than in pots, and if left undisturbed will continue flowering for years. The charming variety *nazarensis* (fig. 22) will make a useful and welcome addition to the number of beautiful forms of this family already at our disposal. It is a dwarf grower, the stem rising about 9 inches above the ground level, and the flowers are very attractive. The standards are transparent white, the falls white dotted thickly with brown, and with a large purplish patch in the centre.—M.

FIG. 22.—IRIS SAARI NAZARENSIS.

where this species of *Iris* has its home, at a height of more than 6000 feet above the sea. The members of the whole group bear a very striking aspect, but it may be noted that there is more of refinement and less of grandiose peculiarity about *Iris Saari* than in *iberica* and its varieties.

Coming as it does from an alpine region, this *Iris* is eminently fitted to endure the rigours of the English climate. There is a peculiar notion prevailing that it is necessary to lift, dry, and store these plants for the winter. The result of this is that many of them perish in the process. The simplest and the best way is to set them out in a bed of rich fibrous loam, fairly moist, and in a position exposed to the midday

FLOWER BED IN PEARSON'S PARK, HULL.

PERHAPS I may be pardoned for asking to be afforded space in the *Journal of Horticulture* for the publication of the enclosed photograph (fig. 23) of a very large and elegant-looking flower bed of original design that was to be seen during the past summer in Pearson's Park, Hull.

We are in no way astonished that under the guidance of Mr. Peak, the park's Superintendent, the public of this city is occasionally afforded an agreeable surprise, for in the west as well as the east parks attention has on previous occasions been called to Mr. Peak's

great ability in turning unsightly corners into features of much horticultural interest and originality. In the present instance, he has succeeded in producing on a single bed what may justly be assumed to be a complete flower garden.

That the design, as well as the style of planting, is original is unquestionably correct, and there need be no surprise if, on a future occasion, further efforts in this direction are brought to light. The position the bed occupies is an ideal one, sheltered and set off as it is by a fine background of shrubs, which are margined with a collection of perennial plants, it being scarcely possible to conceive that within 25 or 30 yards of the bed and beyond the shrubs runs the public thoroughfare.

The bed in question is 25 feet in length by 19 feet in width. The outer edging, as may be noticed on reference to the photograph, is planted at a little distance apart with *Echeveria secunda glauca*, followed by a line of dwarf Golden Box and a second line of *Retinospora plumosa aurea*, and to the inner portion of the bed a third line of *Ajuga reptans*. The four corners of the bed are set off with one

EARLY PEAS.

THE time has arrived when a great number of gardeners make an effort by sowing under glass to hasten the production of the earliest gathering of Peas. Various means are devised, and while pots afford greater facilities for planting, shallow boxes must not be ignored. I say shallow, by which is meant a depth of not more than 2½ inches. Sown thinly in these, the bottoms of which are covered with coarse leaf mould or Mushroom bed refuse before they are filled with the soil mixture. This layer the roots take hold of, and if not sown too soon or forced in heat they transplant readily, and it is surprising how quickly they recover from the disturbance caused by planting.

In deep boxes filled with soil the work is neither so expeditious nor so satisfactory. In shallow boxes the soil becomes almost matted with active roots, which at the time of planting can be divided into small bunches. The slight check, too, that is thus given is regarded by some growers as a means by which podding is accelerated. This, however, depends very much on the weather from that time. Though pots may claim some advantages over boxes, the latter expedite the

FIG. 23.—A BED IN PEARSON'S PARK, HULL

plant in each of *Diplopappus chrysophylla* as distinguishing features. The groundwork, which appears to afford a cheery aspect to the whole bed, is composed entirely of *Antennaria hyperborea*. The scrolls are first lined out with *Pyrethrum selaginoides aurea*, and afterwards filled in with *Armeria maritima*. The rest of the design is planted with the following:—*Alternanthera versicolor grandis*, *Alternanthera aurea*, *Alternanthera magnifica*, *Lobelia* (a fine blue seedling), *Lobelia Swanley Gem*, and *Lobelia King of the Blues*, *Begonia Sutton's Miniature*, and *Begonia Sutton's Fairy Queen*.

It will be observed that throughout the bed there are small dark patches, some of which are square and others circular in shape. These are filled with plants of a suitable character to afford tone to the whole arrangement, and include Golden Thyme, Golden-leaved *Ligustrum ovalifolium*, *Cuphea platycentra*, *Fuchsias coccinea variegata* and *Sunray*, *Euonymus pulchella* and *E. radicans variegata*, with *Vincas major variegata* and *major maculata*. By way of affording relief to the other plants used, a very good effect was produced by placing in suitable positions all over the bed very small shrubs of an ornamental character, as single-dot plants, of *Cupressus lutea*, *Lonicera aurea reticulata*, *Thuia occidentalis lutea*, *Berberis dulcis nana*, *B. compacta*, *Retinospora plumosa argentea*, *R. filifera*, and *R. squarrosa Veitchi*.—J. P. LEADBETTER, *Tranby Croft Gardens, Hull*.

work in sowing, and require slightly less room, items that in the well-appointed garden account for little, but in that in which there is a dearth of labour press into prominence almost every day, and in the spring months in particular.

Except in sheltered gardens, and in warm soils, November-sown Peas do not give a return that will satisfy in the extent of their produce, and often after a spell of frosty weather they are so badly crippled that there remains no other course but to dig them in and plant again elsewhere. It is only in favourable winters that outdoor sowings made in November can be said to be profitable, and since the introduction of the early marrowfat types, the round varieties, which alone are suited for this phase of culture, are fast becoming ousted.

Sown in boxes or pots, and grown steadily in cold pits, they are sturdy, hard, and in otherwise good condition for putting out in March. Even then the state of the weather must be taken into account, and provision made for protecting them against frost visits, for bright summer-like days are treacherous in the extreme. It is always advisable to stake the taller-growing sorts at once, and give additional protection with light boughs of Yew or Fir, inserted on the windward side of the rows. The soil should be in a good planting condition, and the day chosen a mild one, otherwise there is loss rather than gain in the ultimate results.—W. S.

MADAME CARNOT.

THIS variety, which is so well known and highly esteemed by all Chrysanthemum growers, as already recorded in this Journal, has produced an interesting sport that is described as being of a bright crimson which will be likely to become as popular as its parent, provided all goes well with it.

The feeling that the announcement of its advent probably at first occasioned to the majority of the legion of specialists was one of surprise, and in the absence of any authentic, or very definite, information respecting its origin, the question of it being the offspring of one of the sports of Madame Carnot naturally arose. This, if being the case, meant the production of a secondary sport of a crimson colour from a yellow variety derived from a white flowered parent.

In any case the sport is a most interesting one, from the fact of the parent, itself in the fore rank of standard white varieties, having produced sports of such varying colours. It seems that with highly cultivated plants, as with men, it is generally the unexpected that happens.

The silent methods of Nature with regard to both the distribution and limitation of colours in flowers, and the surprising changes effected in some of them, are very mysterious, and the various stages of their progression are difficult to trace. Indeed, when the most precise records are obtained through careful observations, it is by no means certain that a general principle can be established that would avail very much in elucidating the subject in relation to the order of their evolution. But this is a digression.

To revert to the sport in question, which, it is said, is another and very distinct one produced by Madame Carnot from a plant in the possession of Mr. F. Perkins of Oxford, and if, as we have been informed, it was the only one of this variety that he reserved for stock purposes, the circumstance of its appearance and security must be considered as singularly fortunate.—JOHN E. JEFFERIES.

CHRYSANTHEMUM DAMP.

My first experience with this annoying disease was in this wise. On a certain Tuesday in 1898 I was worshipping what to my poor efforts appeared to me a glorious bloom of Mutual Friend; its lovely whiteness charmed me. The following day I returned to my Friend, prepared to bestow a similar amount of admiration. To my horror, many of the petals had very small pink spots scattered over them, and referring to Mr. Molyneux's book, I made up my mind that this must be the so-called damp. By the following day these had greatly increased in size, and the beauty of the bloom was utterly marred. I cut it, and took it to my cook, who is a worshipper of flowers from their cradle to the grave; no stage of decay seems to come amiss to her. Death, floral death, still appears to have charms for her! After lamentations over the bloom it was placed in water; the disease went on rapidly, and by Saturday night it was a mass of brown rotten petals. Later, blooms of Mrs. G. Gover and others went in the same way, and my small array was sadly disfigured.

So much for that year. Last October, on housing the plants, I started the fire, giving generally some small ventilation at night, increasing it during the day. I saw nothing of my enemy till a few days after the opening of November, when there was a good show of bloom, and I had picked out a respectable six for a stand I had entered at a neighbouring exhibition. The weather was so very mild that I dropped my fire altogether for two or three days, and about the third day Mutual Friend, Madame Carnot, Mrs. Mease, and G. J. Warren, and some other whites, were all hopelessly spotted—blooms I had hoped to show. I immediately put on the fire again, and dusted the blooms well with anti-blight powder from my bellows. This certainly appeared to me to check the mischief, so that many of the flowers retained their spotted condition, which at a distance was scarcely noticeable. I may say that my plants were more crowded than I like, and supposing the condition to be contagious it is, of course, an evil.

There is another point that struck me, which is, that the terminal blooms were affected far more frequently than the crowns. Markedly, was this the case with two of the reddish bronze colour—Mrs. G. Gover and Jos. Chamberlain. On the same plant, the former had one crown and three terminals, the latter one crown and two terminals. In both the crowns escaped, whilst the terminals succumbed. With the exception of these two the disease appeared to fasten on the whites and the pale yellows—Mutual Friend, Rose Wynne, Mrs. H. Weeks, with Madame Carnot and its sports. I have only half-dozen incurved,

and of these Duchess of Fife alone was touched. It is hard to say whether shutting off the fire had anything to do with the incoming of the trouble, but I feel convinced that the anti-blight did arrest the trouble, and seeing that prevention is better than cure, hope another season to try and forestall the enemy by dusting early.—Y. B. A. Z.

CRIMSON CARNOT.

IN reply to "Sceptic," page 78, I should like to state a few facts about this plant, which originated nearly 100 miles from Earlswood. The owner wrote asking me what a crimson sport from Madame Carnot was worth, and I could not resist the journey to see the flower, although I felt sure it would be a wild goose chase, as I have had several such. I was soon on the spot, and sure enough there was Madame Carnot in foliage and growth, with a John-Shrimpton-like flower on the top. The plant was a poor starveling in a 5-inch pot, which may account for the shortness of the florets, but there was no mistaking the parent variety in other respects. For the general satisfaction I am leaving the top eyes on the old stem, in hope that they will show flower buds, and if so I shall send specimens to the Editor. I only hope they will come the same colour as before.—W. WELLS.

How quickly "Sceptic" has forgotten of the existence of a Yellow Carnot. Was not G. J. Warren sent out under the name of Yellow Carnot, the name being persisted in until it was found necessary to drop it? Does not "Sceptic" assume a tone applicable to the sour Grape fable about this Crimson Carnot prodigy? What has the introducer of Red L. Canning to say to the assertion made on page 78 by "Sceptic?"—OBSERVER.

DECORATIVE CHRYSANTHEMUMS.

ONCE again Mr. Molyneux furnishes information which, to the gardener who has an extensive supply of cutting material to furnish over a long period, is most valuable, and particularly to a section of the Journal readers who have not the means of proving newer varieties for this particular purpose. There is a limit to the number of Chrysanthemums that can be accommodated by many of the smaller growers, divided between decorative sorts and those to carry specimen blooms, and to these the advice given by Mr. Molyneux is most acceptable.

There is with every class of grower a desire to obtain the most up-to-date his means will allow, and to embark on a speculative selection from catalogues often leads to results that are not desirable. Chrysanthemums play such an important part in the embellishment of dwelling rooms in winter, both in a cut state and in pots, that the matter of selection is an all-important one, and it is distinctly enhanced when there is an additional claim from the conservatory, which, with the dwelling rooms, must be kept gay the winter through. Monotony is favoured when the same old sorts are grown year after year without the introduction of some fresh stock.

I quite agree with Mr. Molyneux, that R. Hooper Pearson is the finest yellow-flowered variety for decorative work, and although a November flowerer, no doubt by pinching and cool treatment it might be had well into December. It would seem that for the purpose of specimen blooms it has not sufficient size to satisfy growers, but its loss in that section, if this is so, must be a gain in the other. As a conservatory plant it apparently possesses every quality. For January flowering the Queen is said to be the best among whites. In a search through some catalogues I failed to find this quoted, and therefore I take it to be quite new, and a speciality from a nursery from whom I have no list by me.

For January flowering sorts there is always an inquiry, and Chrysanthemum specialists having a stock would do well to bring them before the notice of readers by advertising them by name, so that prospective growers would know the source from which they can be obtained. There are not many varieties, either new or old, that can be claimed to be January flowering under natural conditions. While propagation is still in progress this hint may be advantageously acted upon, both for the benefit of the grower and producer.—W. S., Wilts.

DAVALLIA RUFESCENS TRIPINNATIFIDA.—Lovers of Ferns need not be deterred from growing this splendid stove variety on account of its somewhat long name, for it almost surpasses all the Davallias when a well grown plant is met with. Stately and erect it stands, needing no support, its long plumed fronds of a somewhat pale green colour giving tone to any exhibition collection; in fact, for this purpose it is specially to be commended, being a capital traveller and adding weight with the judges by reason of its quality. Good fibrous peat, round red sandstone, a few lumps of charcoal, and a surfacing of fresh sphagnum moss provide the compost requirements, not overdosing with water until the rhizomes wend their way. In the winter time less water is most certainly required; but on no account place in a colder atmosphere, or a mishap will soon occur.—R. P. R.

RANUNCULUS PARNASSIFOLIUS.

MR. RABY's supposition that this is a plant of modern introduction is quite erroneous, as it has been in this country nearly a century and a half. It is a charming alpine plant, very dwarf in habit, with deep green radical leaves and comparatively large white flowers (fig. 24), borne on bold peduncles. It is a native of the Swiss Alps and the Pyrenean mountains, and though always scarce in England, has been long known. Messrs. Kennedy & Lee introduced it as early as 1769, but there is no record that they succeeded in flowering it. Mr. William Curtis was more fortunate in 1797, as recorded in the "Botanical Magazine" of October, 1797. He received roots of this and several other rare and curious plants from M. Neckar de Saussure in 1796, and obtained blooms the following June from which his

FIG. 24.—*RANUNCULUS PARNASSIFOLIUS*.

characteristic figure was taken. He grew it in a small pot of loam and bog earth. Mr. Donn of Cambridge grew the plant in 1818. Messrs. Loddiges found it prosper and multiply abundantly in sandy loam without any winter protection, giving it abundance of water in the summer, rearing the young plants both from the ripened achenes and by division of the roots.

HARDY BORDER FLOWERS.

IRIS SUSIANA.

THE fine illustration of the magnificent flowers that *Iris Susiana* will yield under favourable conditions (such as those which produced the specimen figured in the Journal of January 5th) must have increased the desire of many readers to grow a flower of such wondrous beauty. None of us who have seen it are likely to forget the impression made by its flowers with their strange yet beautiful colouring. It is worth some trouble to obtain such flowers, and whatever method of cultivation we adopt, it is to be hoped that it may be successful. Research among our older writers shows us that they, like us, were not in agreement about its cultivation. We have had different plans, both old and new, laid before us. It may be that what leads to satisfaction in one garden may only spell failure in another. I have been interested to find that Phillip Miller, whose directions some of us find are not so

far wrong as to make us scorn his methods, advocates planting *Iris Susiana* in a moist place. Although Mr. Upex has had to do this for want of a better position, and although one thought he would be unsuccessful there, it is possible that in unconsciously following the teaching of Miller he may be adopting the plan most likely to give flowers in that particular garden. He has evidently, however, made careful preparations to secure that as little moisture as possible should ascend. Whatever our own views, it is only right that readers should have an opportunity of knowing that there are different practices for different gardens.

PAPAVER RUPIFRAGUM.

We have not among the perennial Poppies the variety of form and colour shown by the annuals, many of which, such as those raised by the Rev. W. Wilks, and known to nearly all as the Shirley Poppies, are so beautiful. The perennials are in course of improvement, and it is possible that they may eventually give us a wide range of colour. At present this is not the case, and we are practically confined to various shades of red and orange, with some white or bluish varieties raised from *P. orientale*. Among the Papavers with orange flowers is *P. rupifragum*, whose flowers resemble in colour those of *Papaver pilosum*. There, however, the likeness ceases, as *P. rupifragum* has much smaller flowers, which are produced on long slender stems. The plant itself is not so tall, and the leaves are more cut than those of the Pilose Poppy. Unfortunately the flowers of this species are likewise fugacious, though not so fleeting as those of *P. pilosum*. It cannot be termed either a showy flower or a good border plant; yet it has its uses in the border, and it is a plant some admire a good deal. It is, as yet, not very common in gardens, but as it is readily raised from seeds, it will likely find its way into more before long. It is a native of Spain and Morocco. A variety called *P. rupifragum* var. *atlanticum* is also in cultivation. *Papaver rupifragum* is one of the parents of some hybrids raised within recent years.

AQUILEGIAS.

We could ill spare the Columbines from our flower borders, but for a time they were little seen. They were, one supposes, too "old-fashioned," and were not brilliant enough to associate with the bedding plants which were so popular at the time. Opinion has changed, and the Aquilegias are in favour once more, although the favourite long-spurred varieties are those now most seen. They are charming plants, and show one how adaptable are many of the hardy flowers to change and improvement. With such beautiful flowers at command—flowers which are easily grown—it is not surprising that some of the charming species of the Aquilegias are little sought after. After all, one of the requirements in the border is a plant which gives little trouble. This virtue these hybrids possess, and they are thus to be recommended for those who like graceful and prettily coloured flowers. The colours are very varied, and they cannot be described as they are so numerous. It is these hybrids, which have the vigour of the old *A. vulgaris* and the grace of *A. chrysantha* and other long-spurred species, which one would advise for use in the border. They are easily raised from seeds, and a good strain will give many charming flowers.

Charming as are these hybrid Columbines, the old *Aquilegia vulgaris* is not to be despised, and one finds many visitors to the garden look upon its blooms with delight. They, too, are wonderfully varied in colour. The double forms, once sought after, look lumpy to me, but some view them with more favour. They are only too prolific in their increase from seed, and become very troublesome when they spring up in unwelcome places. Though the foregoing are among the best for the border, there are some of the species so pretty that they would be very ornamental. In its way *A. chrysantha* is very pleasing, with its pretty yellow flowers on stalks 3 or 4 feet high; so is *A. formosa*, with its red and yellow flowers. The scarlet and yellow *A. canadensis* is also worth growing in the border; it is dwarfer than the two last named. Most of the others—such as the exquisite *glandulosa*, *cœrulea*, *pyrenaica*, and *alpina*—are better suited for the rock garden than the border. In the hybrids first named will be found almost all their charms, with that more robust constitution which makes them fit for the greater trials of the mixed border.

While these Aquilegias grow in almost any good soil, they seem to like one of a rather sandy nature. The seeds may be sown in the open, but I prefer to sow the choicer hybrids under glass. The seeds germinate irregularly, and some will remain for a considerable time before showing signs of growth. It is thus well to be careful, in pricking off seedlings, not to disturb the soil in which the seeds were sown any more than can be avoided.—S. ARNOTT.

SWEET PEA GORGEOUS.—English-raised varieties of Sweet Peas are almost matchless in their beauty and habit, and quite sufficient to satisfy the majority of growers. But then there are the numerous connoisseurs who like to test the named varieties, and as the signal has been sounded for a conference, the need of perfect varieties will be readily recognised. Such a one is found in Burpee's novelty *Gorgeous*, a variety with a name which does not belie it, as it is of a shade much richer than anything of the kind seen previously. Not only is it robust, but the flowers are freely produced and the substance correct. A warm rich orange salmon will almost describe it, the flowers being thrown well from the foliage.—PRACTICE.

ROYAL HORTICULTURAL SOCIETY.

THE COMMITTEES FOR 1900.

FULL particulars of the exhibitions of the Society can be had from the "Arrangements for 1900," in which are also given lists of the various Committees, and these we reprint for the benefit of our readers.

SCIENTIFIC COMMITTEE.

Chairman.—Sir J. D. Hooker, K.C.S.I., C.B., F.R.S., V.M.H.

Vice-Chairmen.—Foster, Sir M., K.C.B., V.M.H., Sec. R.S., Great Shelford, Cambridge.

Masters, Maxwell T., M.D., F.R.S., &c., Mount Avenue, Ealing, W.

Thiselton-Dyer, Sir W. T., K.C.M.G., F.R.S., Royal Gardens, Kew.

Hon. Secretary.—Rev. Prof. G. Henslow, M.A., V.M.H., F.L.S., 80, Holland Park, W.

Baker, J. G., F.R.S., V.M.H., 3, Cumberland Road, Kew.

Balfour, Prof. I. B., F.R.S., V.M.H., Botanic Gardens, Edinburgh.

Bonavia, Dr. E., Westwood, Richmond Road, Worthing.

Brown, Dr. Horace, F.R.S.

Burbidge, F. W., M.A., V.M.H., Trinity College Gardens, Dublin.

Church, Prof. A. H., M.A., F.R.S., Shelsley, Kew Gardens.

NOTE.—Members of the Council are members of all the Committees.

GREYIA SUTHERLANDI.

THOUGH this plant has been considered chiefly interesting to botanists it is by no means devoid of horticultural merit, for the bright red flowers are produced in dense terminal clusters (fig. 25), and have a rich appearance. In this country specimens, which are not very numerous, seldom exceed a few feet in height, but in its native habitats, the rocks at Port Natal, it is said to attain the dimensions of a small tree, which when in flower has a very brilliant appearance. The leaves are somewhat fleshy and crenated at the margin. Some are quite smooth, and others densely pubescent, a peculiarity that has been repeatedly noted by several observers. It blooms early in the year. This information will, we trust, suffice for W. Parsons, and in addition be of assistance to other readers.

BEDDING LOBELIA FROM SEED.

THE time is not so far distant when it was impossible to grow Lobelia from seeds to produce plants which would be of compact habit and also produce flowers freely. It was necessary to place reliance only on cuttings which were obtained in early spring from stock plants wintered in the greenhouse. Sometimes these would fail, or an insufficient number would be prepared. This can now be avoided, for if some of the excellent strains are procured, and seeds are sown not later than early in February, an excellent stock of young compact plants may be grown by bedding out time.

Lobelia seed is very small, and requires to be dealt with carefully, and to be sown in heat. Fine light soil, composed chiefly of loam, leaf soil, and sand, ought to be employed. Use a wide, shallow pan, drain freely with potsherds, covering them with a layer of rough material and the compost filled in level to the rim, gently shaking down and pressing level. Although the compost should be moist, it is desirable to water the whole gently before sowing. After draining scatter the seeds on the surface, making no attempt, as is usual in most cases of sowing seed, to sow very thinly. Cover the seed with very fine sand, a mere dusting sufficing. Special attention must be given to maintain the surface uniformly moist, so as to avoid the necessity of watering the soil previous to the germination. This can best be effected by placing a square of glass over the pan and shading with paper. A bottom heat of 60° to 65° will cause the seed to germinate. If the pan can stand on a moist base it will be of great advantage in preventing rapid drying of the soil.

Immediately the seedlings push through the soil remove the shading and gradually dispense with the glass, placing the pan in

plenty of light, but shading from strong sunshine. It will spoil the seedlings to a considerable extent if they are allowed to become drawn by examining them too late at the point of germination. The supply of water to the soil is a matter requiring care with Lobelias when tender seedlings. It is a good plan to sink the pot in tepid water to the rim, and withdraw it as soon as water commences to show on the surface. With good drainage and proper soil this does not saturate the soil unduly, but effectively moistens it without disturbing the small plants.

Growth will progress rapidly in the light and warmth of a heated structure, and it will be evident that the seedlings are becoming more and more crowded, but they are short, green, and healthy. The time has arrived for transplanting them. The best manner of carrying this out is to prepare shallow boxes or pans, properly drained and

FIG. 25.—GREYIA SUTHERLANDI.

filled with a light sandy mixture pressed moderately firm. Lift the seedlings in small patches, and plant them a couple of inches apart, burying them to the seed leaves. Place the boxes in a warm, moist position, and syringe daily until growth commences freely, when water may be given in the usual manner. Retain the plants in a heated structure until thoroughly established. Afterwards give cooler treatment, and when the patches of seedling plants begin to touch each other more room must be given. The best place this time is a shallow bed on a hard bottom in a cold frame, but they may be accommodated in boxes. Prior to the final planting at the end of May, full exposure to air is necessary, but protection must be given against sudden May frosts. One aid in rendering the plants compact and bushy is to frequently top the growths when extending vigorously.

The dwarf compact varieties of Lobelia are the best for massing and edging. The spreading varieties can also be raised from seeds, but they are more adapted for growing as isolated specimens in beds and borders, as well as for pots and hanging baskets.—E. D. S.

THE TULIP TREE.

CONSIDERING the highly ornamental character and hardy nature of *Liriodendron tulipifera*, it is somewhat remarkable that there are comparatively few specimens to be found in the British Isles. Possibly the scarcity arose from a mistaken notion by would-be planters that the tree would not flourish in this climate; also that nurserymen found it more difficult to propagate than, for instance, the Oriental and Occidental Planes, and which are so extensively used as town trees. It is for this latter purpose that my present remarks are chiefly intended, and it would be interesting to learn if there is any specific objection to the Tulip Tree for the purpose indicated. My own limited experience of its adaptability favours its adoption, and I am cognisant of a few specimens flourishing well within the smoky atmosphere of Birmingham, and the foliage of no other tree keeps clearer of sooty or other substance. Moreover, the highly glabrous surfaces of the leaves, changing from a bright green to an intensely bright golden yellow in the autumn, afford a diversity of colouration not possessed by the otherwise desirable and elegant "town" Planes. It would, however, be somewhat presumptuous to expect the street or boulevard-planted Tulip Tree—unless in exceptional situations—to produce its beautiful flowers, and even then not until it had attained an age of from twenty to thirty years.

The tree is perfectly hardy, as proved by numerous fine specimens in different parts of the country fully exposed to the roughest winds and sharpest frosts incidental to the British Isles. The flowers are sweetly scented, and the petals six in number, and the three sepals forming the calyx are prettily coloured with orange, yellow, and red. The leaves are truncate at the point, four-lobed, and similar to a saddle in shape. Hence the tree is also known as the Saddle Tree. The Tulip Tree is a native of chiefly the Western States of North America, where in the deep alluvial soils on the banks of rivers it attains to magnificent dimensions, reaching a height of from 120 feet to 140 feet, with boles girthing up to 20 feet in circumference at 5 feet and 6 feet from the ground. It was introduced into Europe upwards of 200 years ago, and there are specimens of it in England 100 feet high, notably at Longleat, in Wilts. Some thirty years ago the writer had the pleasure of viewing the trees in October, when they were enriched with a mantle of golden hued foliage. The Longleat strong loamy soil evidently suited the Tulip Tree, though it will also flourish in light soils.—W. GARDINER.

STUMP-ROOTED CARROTS.

Most Carrot growers have some favourites among the large list which every seed catalogue furnishes, and there can be no doubt that many persons are attracted by the models therein illustrated, while others are fascinated by the splendid examples that are exhibited at summer shows by the leading vegetable growers, and order those which are thus represented. Some may obtain roots almost a counterpart of those seen the previous season, while others are disappointed because the crop does not realise their ideal. There are some soils that will, with ordinary cultivation, produce beautifully shaped Carrots, and there are gardens in which it is almost impossible to grow shapely roots at all. Such cases demand special preparation of the soil, or provision made for exhibition purposes, especially for the long and intermediate types.

For household purposes—and Carrots, it may be said, are in request almost every day—I have for some time held that the stump-rooted or Horn varieties are better than the long roots, and this opinion has been gaining greater prominence for the past two or three hot summers. I am of the opinion that they are more easily prepared and less wasteful when they pass to the kitchen, and though their culture needs the same detail, lifting and storing of the matured crop are much less arduous than the deeper-rooted Carrots demand.

The long Carrots are in most cases grown for winter use, the stump-rooted types finding favour for the summer months only, and often these are sown in small quantities, so that the roots may be drawn in a young and tender state. Thus treated many fail to learn to what a large size they attain when they are sown fairly early and allowed to develop their true character. It is curious how one clings to old customs and old favourites in the matter of vegetables. So many gardeners follow the same course year after year, and are nervous in making new departures for fear they should not equal the old. I believe this to be the case with the crop under notice. Although Carrots may be said to be an everyday vegetable, it is only in isolated cases where there is a difficulty in maintaining a regular supply, and they are so accommodating that periodical sowings may be continued for six months outdoors.

Many seedsmen have their own specialities in both long and short Carrots. There is, however, a preponderance of the latter, and ample to supply the four seasons of the year in every household from the smallest to the largest. The Early Nantes, which is such a favourite for summer use, makes an excellent winter Carrot, and grows to a size sufficient to meet every cooking purpose, and in suitable soils assumes a colour and shape that can scarcely be surpassed by any other. Williams' Matchless is another beautiful variety, either for summer or winter. Early em, Model, Guerande, Summer Favourite, Improved and Champion

Scarlet Horn, are only a few that occur as one writes, and from which growers may easily suit themselves if they so wish. These remarks, it will be observed, are directed towards the more general adoption of the stump-rooted varieties for winter purposes, and in so doing I am persuaded that if these were compared culturally and economically with the long roots, there would be found a favourable balance in their favour.

Carrots, like Parsnips and Beetroot, are better stored in the soil outdoors, and in lifting and laying them in during the late autumn months, proof can easily be obtained bearing on the question of labour. Such sorts as Long Red Surrey and Altrincham are quite uncalled for in domestic uses, and those who adhere to them for winter storing would be surprised if they took the trouble to compare them point by point with the smaller stump-rooted section.—R. ASHTON.

SOIL FERTILITY.

GARDEN EXPERIMENTS *versus* LABORATORY ANALYSES.

SOME modern scientific authorities who have made the soil in its relation to the production of plants and crops a special study, and who do not conduct analyses as a matter of business, appear to attach much less importance to ordinary analyses of soil in the laboratory than to practical experiments in the garden for determining what particular ingredients the soil lacks for the proper support of different kinds of crops. Mr. Herbert H. Cousins, M.A., Lecturer in Chemistry at the South-Eastern Agricultural College, Wye, has some trenchant remarks on the subject of soil analyses in his Primer, "The Chemistry of the Garden."

While he admits the modern "fertility" analysis, by which is determined the "available" plant food in the soil, is sound and reliable, he does not hesitate to brand the old so-called "complete" analyses, based on the determination of the ash found in plants, as utterly fallacious. He goes so far as to say that those well-intentioned persons who, after consulting Professor Wolff's table of ash analyses of various plants, and founding thereon manure formulæ for the different plants, are "blind leaders of the blind."

Mr. Cousins bases his conclusions on stated "facts." 1, The ash of a plant depends directly on the manures with which its roots come in contact. 2, That as a root is obliged to absorb any different salt in the soil the mineral substances of any kind of plant must be variable. 3, The unknown and highly variable proportions of good constituents in a soil is a serious disqualification of the presumptions of the "plant ash oracle." 6, A large or small quantity of plant food in the ash of a certain plant does not preclude the possibility of the plant with the small proportion requiring as much, or even more, assistance from a particular fertiliser than another plant containing a far larger proportion of the ingredient in question.

He goes on to say "A careful series of field (or garden) experiments will teach a farmer (or gardener) more about the profitable manuring of his crops than all the analyses which have ever been made." After those strong pronouncements our author concludes thus:—"Ancient fallacies die hard; and it is urgently needed that some high authority, such as the Royal Horticultural Society or the horticultural institutions connected with County Councils, should approach this extremely crucial problem of the profitable and rational manuring of garden plants by the *only* sound and certain method possible—namely, careful and scientific experiments on actual cultivations year by year."

If those views were not largely, if not entirely, held by the accomplished Principal of Wye College, Mr. A. D. Hall, he would scarcely have circulated the following instructions under the heading of

EXPERIMENTS ON MANURING.

The following suggestions are intended for gardeners, teachers, and others who wish to illustrate the principles of manuring, or to test by experiment what sort of manuring is likely to answer best on their own soil.

SIZE OF PLOT.—A piece 2 rods (11 yards) by 4 rods (22 yards) is a convenient size, larger or smaller according to the number of trial plots.

SITUATION.—Choose as uniform and level a piece of ground as possible, which has all been cropped in the same way in the previous year. It is preferable that the long side of the plot should run across any slope in the ground that may exist, and the drills should run the long way of the plot. If the land is level the drills should run N. and S., rather than E. and W.

CULTIVATION.—The artificial manures used require just as much cultivation of the soil as dung; the whole plot should be dug and bastard trenched in the winter or early spring. This ought to be done in one operation; if part is done at one time and part at another, variations may be set up in the crop. If the digging cannot be done

at once, let the successive pieces run as the drills will be drawn later, *i.e.*, the long way of the plot.

TIME OF PUTTING ON THE MANURES.—When lime, basic slag, or kainit is used they should be sown broadcast before digging in the winter. Superphosphate should be put on just before the first sowing and scuffed in with the hoe. Nitrate of soda and sulphate of ammonia should be reserved till the plants have made a leaf or two.

SUITABLE CROPS.—Beans, Peas, all the Cabbage tribe, Parsnips, Turnips, Potatoes, and Onions.

MANURES REQUIRED.—Nitrate of soda or sulphate of ammonia to supply nitrogen. Basic slag or superphosphate to supply phosphoric acid. Kainit to supply potash. Lime.

It will depend on the amount of lime in the soil whether nitrate of soda and basic slag, or sulphate of ammonia and superphosphate, should be used. If there is any doubt on this point, an even slice of the soil to a depth of 9 inches, and weighing at least a pound, should be sent to the South-Eastern Agricultural College, where an examination of the soil will be made and advice sent.

The quantities required are 2 ozs. per square yard of nitrate of soda, sulphate of ammonia, and kainit; 4 ozs. per square yard of basic slag or superphosphate, and 1 lb. per square yard of lime.

Of course, many other manures will supply nitrogen and phosphoric acid, but the above are the most convenient.

PLAN OF EXPERIMENT.—A. *Simplest, 4 or 5 plots only.*

Plot 1.—Receives nothing.

Plot 2.—Receives basic slag (or superphosphate) only.

Plot 3.—Receives nitrate of soda (or sulphate of ammonia) only.

Plot 4.—Receives basic slag (or superphosphate) and nitrate of soda (or sulphate of ammonia).

Plot 5.—Receives basic slag (or superphosphate), and nitrate of soda (or sulphate of ammonia), and lime.

Plot 5 may be omitted, or a plot may be added which receives dung.

B. *More complete, 6 or 7 plots.*

Plot 1.—Receives nothing.

Plot 2.—Receives basic slag (or superphosphate) and kainit, *No nitrogen.*

Plot 3.—Receives nitrate of soda (or sulphate of ammonia) and kainit. *No phosphoric acid.*

Plot 4.—Receives nitrate of soda (or sulphate of ammonia), and basic slag (or superphosphate). *No potash.*

Plot 5.—Receives nitrate of soda (or sulphate of ammonia), and basic slag (or superphosphate), and kainit. *Complete.*

Plot 6.—Receives nitrate of soda (or sulphate of ammonia), and basic slag (or superphosphate), and kainit, and lime.

Plot 7.—Receives dung only.

Interpretation.—The effect of the manures is to be learnt by comparing the completely manured plot 4 in A, 5 in B with each of the other plots. Taking the B plan as an example:

5 v. 1 shows effect of artificial manures.

5 v. 7 shows comparison between artificials and dung.

5 v. 6 shows effect of lime.

5 v. 2 shows effect of nitrogen.

5 v. 3 shows effect of phosphoric acid.

5 v. 4 shows effect of potash.

MANAGEMENT.—Divide the long side of the piece into as many equal parts as there are to be plots, and at each point of division drive a stout stake 3 feet long till 1 foot of the stake is out of the ground. Repeat on the other side of the plot. When sowing the manures stretch a line across the piece from stake to stake to mark out the plots. Only sow manure when there is no wind.

Draw the drills the long way of the piece, so that each crop runs across all the plots, as shown in the diagram.

Plot 1.	Plot 2.	Plot 3.	Plot 4.	Plot 5.	Plot 6.	Plot 7.	
.....	Peas.
.....	Beans.
.....	Parsnips.
.....	Turnips.
.....	Cabbages.
.....	Potatoes.
.....	Onions.

When the seeds are up, stretch the line from stake to stake again, and scuffle along the line with a hoe to mark plot from plot.

When planting out Cabbages, &c., setting out Turnips, &c., see that there is an equal number of plants in each plot.

It is best to divide the nitrate of soda for each plot into as many equal parts as there are drills, and put each drill's share on at the proper time—*i.e.*, when the plant is beginning to grow a little above ground.

The root crops should be weighed, the whole of one or more drills should be lifted at a time, the roots from each plot made into separate heaps, rubbed to free from soil, and weighed.

The stumps should be left down at the end of the season, and the same manures applied to the same plots the following year, but the position of each crop should be shifted. In a year or two the effect of each manure will be plain to the eye; in the first season the effect will probably only be seen in the weight.

On application to the South-Eastern Agricultural College any further information that is required will be gladly sent.*

THE YOUNG GARDENERS' DOMAIN.

CARROTS.

At present Carrots are grown more or less in every garden, as they are always found useful. For early sowings a hotbed should be formed of leaves and litter some time prior to sowing the seeds, as it will give it time to settle and cool down. About the middle of January is a very suitable time to make the first sowing. Sow thinly in rows about 8 inches apart in light soil, and do not cover the seeds too heavily. Give a thorough watering, but afterwards be sparing with water till the seedlings appear above the surface. Protect the seeds at night, or any other time if the weather be severe, by covering the frames with mats or litter. Sowings should be made fortnightly if the supply has to be maintained.

About the middle of February sowings can be made on sheltered south borders if the soil is light. Have the rows about the same distance asunder as above mentioned, and thin the seedlings a little when they are large enough to handle. The month of March is the time for the main crop to be sown, so prior to this the ground should have been thoroughly prepared. No hard and fast rule can be made as to the date they should be sown, as it greatly depends on the weather; but always choose a fine day when the ground is in workable condition, for sowing when it is raining, or the ground is wet, will cause the seeds to come up very irregularly. Have the rows at a distance of 12 inches apart, thus giving plenty of room for the necessary work during the summer months.

When the seedlings are up, and the rows can be distinctly seen, it is good practice to run the hoe between them to loosen the soil and destroy weeds. Thin a little when the plants are large enough to handle, and always choose a dull or showery day for this operation. During the growing season it will prove beneficial to the plants if a little soot is scattered between the rows and hoed in. Before any frosts set in the roots should be lifted and stored in sheds for winter use, and if they are laid in sand they will be found to keep in a good condition. —P. R.

THE CROTON.

With the advent of the new year, those whose demands for decorative plants are large will certainly turn their attention to this valuable family. For use during the dark winter months a well coloured and finely balanced Croton is difficult to beat. They are easy rooting plants, and are propagated by cuttings and by "ringing." The former method is employed for small stock, while the latter process is that mostly employed for large heads.

In taking cuttings care must be observed to obtain the best coloured tops, remembering that the leaves of the cutting form the foundation of the specimen later on. Insert the cuttings singly into thumbs, and plunge in a brisk bottom heat. In a few days they will be found to have emitted roots, and must then be gradually hardened to the temperature of the stove.

If "ringing" is the mode employed, run the knife round the bark twice, in parallel lines about one-sixth of an inch apart, taking the bark out between the cuts. Have a handful of moss ready, and tie round the cut, shaking in a little silver sand. If kept moist the plant will soon throw out roots, and can be cut off, potted, and treated afterwards in the same manner as the cuttings. When well rooted the plants may be shifted into 48's, this size being found the most useful for general use. If larger are required they may be repotted as the roots find the sides of the old receptacle. For compost, use two parts of good loam to one of peat, with a sprinkling of silver sand, and a little Clay's fertiliser. Grow the plants in a temperature of 70° Fahr., with a rise to 85° by sun heat.

To obtain the fine markings and colouring of the plants they must be exposed to all the sun and light obtainable; only some of the more delicate varieties will need a slight shade during the hottest part of the day. Great attention should be paid to the cleanliness of the

* Possibly this may only apply to persons in Kent and Surrey, by the County Councils of which the College is supported.

plants; red spider especially must be battled with. Apply the syringe thoroughly twice a day, getting well underneath the leaves. Being gross feeders, frequent applications of liquid manure are necessary when the pots become full of roots. As the days shorten the syringe must be used more sparingly, allowing the tissues of the leaves to harden somewhat, thus preparing the plant for use indoors.

While small leaved varieties are the most useful for table work, the broad leaved ones should not be overlooked, as their noble appearance contrasts well with the light graceful look of their neighbours. *Angustifolius*, *Aigburth Gem*, *interruptus aureus*, *picturatus*, and *aigburthiensis* are good narrow leaved varieties, and *Emperor Alexander III.*, *Queen Victoria*, *superba*, *undulatum*, and *Mrs. Swan* are well worth growing as broad leaved types.—H. C. D.

HARDY FRUIT GARDEN.

Apricots.—Examine the trees on walls before the buds swell and the flowers show to see that no superfluous wood is retained. Superfluous wood will be that which produced the last season's crop in cases where the fruit was borne on young shoots, and these can now be dispensed with, training in their place successional growths all over the trees, furnishing the available space with fruiting shoots. Apricots, however, do not usually carry the whole crop on the previous year's shoots. The trees bear freely on spurs, some of which form themselves naturally, while others may be induced to do so by shortening the superfluous young shoots to within an inch of their base. These are termed artificial spurs, and increase the productiveness of the trees provided they are not originated too thickly. If weak or exhausted branches have to be cut out the remainder will require re-arranging. Young shoots may be trained in about 4 inches apart, and if shortened, prune to a triple bud.

Peaches and Nectarines.—The pruning, re-arranging of branches, and training of these fruits on outdoor walls must follow attention given to Apricots. Cut out old and half-exhausted, also weak and immature wood, and thin the remainder if likely to be too crowded. The young shoots may be secured 4 inches apart. The best fruit is produced on the young wood, spur growths not generally being originated on Peaches and Nectarines. Before all the young wood not wanted is cut out dispose the main branches on the wall, secure them, and follow with the secondary branches, then nailing in the fruiting wood at the distance of 4 inches apart. The superfluous shoots may be cut out entirely. As a rule it is not necessary to shorten them unless there is not sufficient room for the shoot, or it is of too strong character.

When shortening, care must be exercised not to cut the shoots to a blossom bud. It must either be to a single wood bud or a triple bud, as it is very necessary for the extremity of each shoot to form growth which shall extend and attract sap through the whole shoot for the benefit of the fruit. A triple bud consists of two fruit or blossom buds with a wood bud in the centre. Wood buds may be distinguished by their character, as they are thin and pointed, and contain a growing point, whereas blossom or fruit buds are round and plump, enclosing stamens, petals, and pistil, the essential reproductive organs, in a rudimentary state.

Avoid fastening the shoots tightly with the shreds or placing nails in extremely close proximity to the branches. After the training has been finished it is a good plan to syringe the trees with a mixture of sulphur and soapy water; but if the trees have been seriously infested with red spider or any other pest they should receive a preliminary dressing with a stronger and more effective insecticide prior to re-arranging and training.

Pruning Gooseberries.—When the winter pruning has been deferred to the present time, the first opportunity should be taken to carry out the work. Bush trees may first be subjected to a general thinning, reducing the material in the centre as well as branches near or descending to the ground. A fair quantity of young shoots ought to be retained without any shortening; some may be left at 6 inches, and the remaining pruned back to form spurs, cutting them to within an inch of their base. Large bushes ought to have a space of 6 feet between them. It is impossible to properly thin and prune the bushes if they are allowed to remain too thickly together.

Gooseberries are often treated on the same system as Red and White Currants, but it is a mistake to do this if the buds are attacked by birds, as there will be few left to produce fruit. The best system is either to thin out the bushes by the removal of the most crowded portions, or to reduce the superfluous shoots to within an inch of their base, the others being left at full length or partially shortened, but it will be useless to do the latter with any shoots denuded of buds.

Red and White Currants.—The pruning of these should now be completed. In a properly established bush the branches will have been originated at equal distances, hence no thinning-out of main branches is, as a rule, necessary. In time, however, branches deteriorate, making it imperative to cut them out, replacing them with strong young growths from the base. The side shoots on the established main branches ought now to be shortened to within an inch of their base. The leading shoot on each branch must also be pruned closely if extension has ceased, but in the case of young branches the leading shoot is annually shortened to 8 or 9 inches until the full length of the main branch is reached. The side shoots are pruned in the usual way, but summer pruning is also essential.

Black Currants.—The vigorous growths produced by Black Currant bushes annually are the most suitable for bearing fruit. If the bushes are kept well replenished with such, without overcrowding, there will be ample crops of fruit. The old shoots may be freely cut out, as they only serve to crowd and weaken. Dead wood must be removed whenever seen, and weak shoots ought to be dispensed with.

American Blackberries.—The annual growths of these are long, and in pruning simply require to be shortened one-fourth, as this portion is rarely if ever sufficiently ripened to bear fruit. The fruiting canes of the previous year may be cut out entirely.

FRUIT FORCING.

Cucumbers.—*Raising Plants in Frames.*—The old-fashioned and still excellent method of growing Cucumbers in pits and frames has not been entirely superseded by the hot-water pipes system, and persons who do not sow seeds before February often cut fruits quite as early as some do with an inadequacy of heat-furnishing material, and who sow at the new year. The material for making the bed for raising the seedlings being in a fit condition through turning and mixing with leaves, so as to induce a sweet regular heat, a site for a bed should be chosen with a full southern aspect, and having shelter to the north, such as that of a hedge or wall. If the ground be rather higher where the bed is to be formed than the surrounding level all the better. Mix and beat the materials well down as the work proceeds, using the fork, and making the bed about 5 feet high at the back, and 4 feet 6 inches in front, which will allow for settling, as it will do about one-third. A few Pea sticks placed across and along the bed at intervals not only prevent overheating, but admit the heat from the linings being conveyed to the interior of the bed.

For early work frames with an inner lining are advantageous. They are formed by placing quarter-inch boards 11 inches in depth at the back, and 9 inches in front, with the bottom edges level with the bottom of the box, and then the boards, which form an inch cavity all round the inside by affixing them on strips of wood an inch wide and thick nailed on the inside of the box, and thus top heat is furnished. In a week after making up the bed and putting on the frame and light, level the surface of bed, replace the box and put in sufficient sweetened fermenting material to raise the inside to within 4 inches of the inner frame or casing, placing partially decayed rather dry leaves or sifted spent tan on the manure for plunging the pots.

Peaches and Nectarines.—*Earliest Forced House.*—The trees will need an occasional syringing after the fruit is set to assist them in casting off the dead remains of the flowers, and when the weather is bright they should be syringed every morning and afternoon when the fruit is swelling freely in order to keep down red spider. If, however, the weather be dull, the syringing must be practised early in the afternoon, so that the trees may become fairly dry before night, or if that does not take place, the afternoon syringing must be dispensed with, damping the paths and borders instead, as keeping the trees dripping with water through the night causes weak growth, thin foliage, and discoloured points of the leaves. Water the inside border with liquid manure, which will assist the fruit in swelling, especially in the case of weakly trees long subjected to repeated forcing.

Vigorous trees will not require stimulants, excessive vigour being unfavourable to the fruit safely passing the stoning process. Remove a few of the worst placed and surplus fruits, but thin carefully until the fruit is the size of a small marble. Disbudding also must be performed carefully and gradually, leaving a growth at the base of each bearing shoot, and another at its extremity, or at least level with the fruit. The shoots retained for attracting the sap to and supporting the fruit should be stopped at the third leaf, but the basal shoots must be trained to take the place of those now bearing fruit. Shoots upon extensions must be left 12 to 15 inches distance apart to form the bearing shoots of the future. It is a great mistake to crowd the trees with growth for which there is not space enough to allow of its full exposure to light and air; therefore avoid overcrowding, seeking to maintain an equal balance of growth throughout the trees, and its solidification by judicious ventilation.

Second Early House.—Trees started at the new year will be in blossom, and should have a temperature of 50°, 5° less on cold nights, 50° to 55° by day artificially, and 60° to 65° from sun heat, not allowing a rise above 65° without full ventilation. Lose no opportunity of admitting air, ventilating from 50°, avoiding, however, cold currents, and leave a little ventilation constantly at the apex of the house. Damp the surfaces occasionally to secure a genial atmosphere, but avoid a close saturated one. Shake the trees on fine morning to disperse the

pollen, or brush the blossoms over lightly with a rabbit's tail mounted on a small stick, or apply the pollen to the stigma with a camel's-hair brush.

Houses Started Early in February.—The trees to afford fruit in July must now be started, they having commenced to swell their buds naturally. Syringe the trees until the blossom buds show colour, but not too frequently, always allowing them to become dry at night. Discontinue the syringing after the anthers show, but sprinkle the paths and borders once or twice a day to maintain a genial condition of the atmosphere, avoiding a close stagnant one. If the flowers are very numerous thin them by rubbing the hand downwards on the under side of the shoots, which will strengthen the remainder, enabling them to set better. Examine the trees closely, and if there be any aphides fumigate with tobacco or other insecticide, so as to destroy them before the flowers expand. Maintain a temperature of 40° to 45° at night, and 50° by day, above which ventilate freely. When the flowers expand raise the temperature to 50° at night, 55° by day, and 60° to 65° from sun heat with free ventilation. On cold nights the temperature may fall to 45°, or even less, also 50° by day when cold, allowing a little ventilation constantly at the top of the house.

THE BEE-KEEPER.

PRESERVING THE LIVES OF BEES.

In a general way bee-keepers are on the alert to strengthen their stocks when the honey harvest is drawing near; but do they take steps to preserve the lives of the bees during the dark dull days of winter, when the queen has ceased her maternal labours for a season, and each bee lost or destroyed means one unit less to preserve the warmth of the cluster? This is a subject that requires more than passing notice. We are convinced it is only necessary to draw the notice of bee-keepers to this important matter for them to realise how beneficial it would be to the bees if more attention were given to them at this season.

Preserving the lives of the bees may be done in a variety of ways. Should there be a fall of snow and the sun shine brightly for an hour or two during the middle of the day, the bees will leave their hive by hundreds, many of them never to return. If anyone doubts this fact they can soon be convinced, after a fall of snow, by observing how numerous the dead bees are in close proximity to the hives. Stocks may be seriously weakened from this cause alone. The preventive we have given in previous notes.

Serious losses also occur from other causes which are not so visible to the ordinary observer—namely, the numerous bees destroyed by birds. In the autumn birds are sometimes troublesome in this respect, but as the old bees are then dying at a rapid rate there is not much harm done. During November and December the stocks do not seem to be much molested. Directly, however, the days begin to lengthen they swoop down to the hives by the score. The chief culprits are the tits and common house sparrows. A pair of the former will probably destroy as many bees in half an hour as half a dozen sparrows would in a day.

It is interesting to watch the tits when there are not many bees on the wing, and to observe their cleverness in enticing the bees to leave the hives. They work most systematically. If there are thirty hives in a row they will carefully examine the surroundings of each to see if there are any stray bees that are unable to return to their hive. These are at once taken to the nearest tree and dissected. The head and sting are discarded, and only the abdomen is consumed. We have seen a bird treat half a dozen bees in this manner in less than a minute; this was after snow, when numerous bees had been tempted by the bright sunshine to leave their hive and had become benumbed.

The tits, however, have found out that it is only necessary to make a noise at the entrance to the hive to attract the attention of some of the bees. Thus they fly from one alighting board to the other, tapping with their beaks as they alight. Any stray bee is immediately seized and treated as described above. The birds appear to be most ravenous in this respect, and unless steps are taken to destroy them it is only reasonable to suppose that a strong colony of bees may be much reduced from this cause alone.

Sparrows do not watch the hives so closely as the tits, as they can obtain a variety of food. It is, however, necessary, to take some steps to destroy both the tits and the sparrows where they are so troublesome. The former are easily taken in an ordinary V-shaped mousetrap baited with meat or bread. We never interfere with them at any other time, as they doubtless do much good in other directions. Sparrows can also be trapped in the same manner, but they are more wary. If their roosting places are observed, they may be easily netted on dark nights.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Apple Hollandbury (D. W.).—The following description of this handsome Apple is from Dr. Hogg's "Fruit Manual":—"Fruit, very large, 3½ inches wide, and 3 inches high; roundish and flattened, with irregular and prominent angles or ribs extending from the base to the apex. Skin, deep yellow, tinged with green on the shaded side, but bright deep scarlet where exposed to the sun, generally extending over the whole surface. Eye, closed, with long acuminate segments and set in a wide and deep basin. Stalk, short and slender, inserted in a deep funnel-shaped cavity, which is generally lined with russet. Flesh, white, with a slight tinge of green, delicate, tender, and juicy, with a brisk and pleasant flavour. A beautiful and showy Apple for culinary purposes; it is in use from October to Christmas. The tree is a strong and vigorous grower, but not a very abundant bearer. It succeeds well on the Paradise stock.

Average Crop of Mushrooms (Jardinière).—A full crop is, as we have determined by several years' experience, 1 lb. per square foot of bed surface, the Mushrooms being full grown or "broilers." Sometimes this rate of production is exceeded, though not often; and in most cases "buttons" are found detracting somewhat from the weight, yet not always of the value. There is, however, a great difference in the yield of beds, and records of minimum produce are necessary to strike an average. These we cannot determine. We found 4½ lbs. per square yard of bed, or half a pound per square foot, profitable culture. At this rate your bed of 800 square feet should yield 400 lbs. of Mushrooms.

Old Plum Trees against a Wall (Idem).—The procedure you illustrate and describe is correct for trees making strong growth and not producing fruit for many years. The manipulation of the heads of the trees also appears from the sketches before and after pruning to have been judicious as far as it goes, but we would have preferred to cut the leader back one-third of its length and the side branches two-thirds, and from these taken forward well placed growths from each. Young leading and side branches would then have been secured, which in two or three years would form spurs and give fruit abundantly. As it is, the side branches cut off close to the stem cannot produce young growths, though these may issue at the point on the stem, and the more promising should be retained in place of the branches cut away, having them 12 inches asunder. A portion of the bushy head should be left on the top of the branches, for the object is, or should be, to get new growths; train them fan-fashion from as near the base as possible, then the trees will take on a new lease of life and give good fruit.

Crotons (Young Gardener).—Where a brisk moist heat can be maintained young healthy plants may be potted at once. Be careful that the soil in which they are to be potted has been thoroughly warmed, or a severe check may result. The plants should be potted in the house in which they are to grow. Careful watering is necessary after repotting at this period of the year. Plants that have become bare at the base may be notched near the top and mossed. As soon as growing conditions are favourable they will form roots, and may be taken off and be placed in small pots, but as in the case of cuttings they must afterwards be watered with discretion.

Stocks for Budding Roses (Homo, S.).—There is no exclusively best stock for Roses. The common Dog Rose of the hedgerows is the sole stock used for standards, as no other has been found so suitable in practice. Stocks obtained from seed of this plant, and called seedling Briars, are much favoured in some establishments for dwarf Roses, particularly Teas. The Manetti is also largely employed for dwarf Roses. It is not, however, so popular as formerly, as the strong-growing Roses attain too much vigour for ripening the wood, and the vigour derived by the weak growers is only transitory, and thus is not approved for all varieties or for all situations. The De la Grifferaie has been used to some extent, and has gradually risen in favour, especially for Tea-scented Roses. We have had equally good results from Briar stocks both raised from cuttings and from seed.

Aralia Sieboldi (R. F.).—The plant presented the appearance of having received a check to growth, but there was no evidence of this taking place at a particular stage, all the leaves being similarly affected. It was not very well rooted, having recently been repotted, though the roots, both in the old ball and in the new soil, were, so far as we could discover, quite healthy. On the leaves we noticed a slight rust, such as occurs in Begonias infested by *Tarsonymus* species, but we failed to discover the pest. Perhaps vaporisation with nicotine would give relief, repeating two or three times at intervals of a few days. It is a very difficult pest, however, to eradicate when it obtains a footing upon plants, and spraying with the nicotine diluted to a safe strength, say 1 part in 100 parts water, and wetting the plants on the under as well as the upper surface of the leaves, appears the best preventive and remedy. We have also found tobacco water useful against it.

Calcined Bones as Manure (J. C. S.).—The burnt or calcined bones are an excellent phosphatic manure, bone-ash ranking higher than mineral phosphate. The burning or calcining destroys the organic matter and nitrogen but leaves the mineral constituents of the bone, mainly tribasic phosphate. As you say the bones would have to be powdered, we presume they have not been reduced to ash, but are practically bone charcoal. You may use the burnt bones either rough or powdered, the phosphoric acid being yielded much slower by the former than the latter, 4 ozs. being a good dressing per square yard for flower beds and fruit borders, but double quantity may be used with advantage in many cases, pointing in and mixing with the surface soil. For plants in pots a handful or 4 ozs. may be added to each peck of potting soil. You will of course add other fertilisers to the compost.

Mixing Lime with Soil for Tomatoes (R. F.).—The quantity of hot lime, or unslaked—that is, freshly burned—is 1 to 1½ lb. per square yard; the greater quantity when the soil is heavy. The lime should be placed in small heaps, and be sprinkled with sufficient water to cause a fine apparently dry powder. It should then be spread evenly on the ground, leaving it there for a day or two, and then digging in, taking small spits, so as to mix evenly with the top soil. Salt does good in preventing a rank growth of Tomatoes in rich soil, and should be applied a month or six weeks in advance of planting, 3½ lbs. per rod being sufficient, distributing evenly on the surface, and leaving there, as the rain or watering will wash it in fast enough. But kainit is better, at the rate of 3½ lbs. per rod, and instead of lime basic cinder phosphate, 14 lbs. per rod, and there will be supplied phosphoric acid, potash and magnesia, as well as lime and salt, quite sufficient in most cases as correctives. If the soil is very rich, and inclined to sourness, double the amounts of kainit and basic slag may be used, pointing in after applying, and a month or six weeks in advance of planting.

Insects in Soil (H. M.).—The specimens are of *Lipura fimetaria*. It is very common, and may be found in damp earth throughout the year, often engaged in browsing upon Carrots, Potatoes, or other roots. It is usually associated with dead and decaying vegetable matter, and is prevalent on the root-stocks of Primulas, and also on Cyclamens and Freesias. The pests are easily killed by hot water, at a temperature of 110°, which does not injure the roots of plants to which it is applied, except those of a very delicate nature. Lime water made by placing a lump of quicklime about the size of a clenched hand in about 3 gallons of water, stirring well, leaving exposed three or four days, then using the clear liquid only, as in an ordinary watering, will either expel or kill worms, also root mites, and the "white worms" which sometimes cause sickness in plants. There was a specimen in your soil of the "white worm," *Enchytræus Buckholzi*, which attacks the roots of various plants, and appears to like the more or less decayed, rather than the healthy. Not one of the pests named would arise from the use of liquid manure from a tank in which soot and sheep droppings in a bag were placed. Only healthy and free-growing plants can profit by liquid manure, hence it must be used with judgment, and not given to everything indiscriminately.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (N. S. C.).—1, *Freesia refracta alba*; 2, *Begonia nitida*; 3, *B. Gloire de Lorraine*; 4, *B. Gloire de Sceaux*; 5, *B. metallica*; 6, unrecognisable. (W. E.).—1, *Raphis flabelliformis*; 2, *Phoenix rupicola*; 3, *Areca lutescens*; 4, *Kentia Belmoreana*; 5, *Cocos Weddelliana*; 6, *Chamærops humilis*. (Amateur).—1, a poor form of *Odontoglossum crispum*; 2, *Cypripedium insigne*, true; 3, *Cymbidium Lowianum*.

AGRICULTURE IN QUEENSLAND.

WE live in a tiny island, in the least of the continents, far out to the N.W., and yet we wield such a power and possess such vast tracts of land as to influence the whole civilised world. Practically we have annihilated time and space. We are in close touch with all our colonies, and there are few families who have not sons and daughters in all places of our dominion. It does not feel so much like banishment to live in a country of English-speaking folk, where the manners and customs are like those at home, and the climatic conditions much the same. The ships are so well found, and the voyage is made so quickly, that people think no more of a run to Australia than they did fifty years ago of one to America.

We have just been reading with great interest some accounts of the agricultural situation in the great province of Queensland that were supplied by the Agent-General for that country. Perhaps we might suggest that the reader turns to the Atlas, he will then see how vast a province this is, stretching from the temperate to almost the torrid zone.

Its area is 668,497 square miles, as against England and Wales with only 58,186 square miles, so there is no lack of space or variety of climate. It has a good seaboard, 1500 or 1600 miles of South Pacific, and the greater half northwards of the Gulf of Carpenteria. In 1891 the chief exports were wool, gold and sugar; it is now developing and opening out many other sources of revenue, things that we do not count as among our agricultural products.

It appears that Queensland, like other parts of Australia, is subject to long and excessive droughts, and that the droughty season of 1898 sadly affected the pastures and caused a great falling off in the export butter trade. This butter has made for itself a name and place in the London markets, and it is now one of the staple industries of Queensland. The farmers are quite alive to the situation, and are endeavouring by breeding and better care of their cattle and by the best of dairy management to secure a first-class article. Shipments are made fortnightly to Great Britain. In 1898 in spite of the drought, 391 tons were forwarded to England, and it is expected when the estimates of 1899 are ready that it will be found that something like 1000 tons have been exported.

Really good butter will always command a good price. We hear far less nowadays of butter at 5d. and 6d. per lb.; the seasons have not altered, but the management has altered—the work of the travelling dairy school is beginning to tell.

The next item on the list is foreign to us. We do not cultivate the plant except as an ornamental and sweet-scented addition to our gardens, or as a personal indulgence of doubtful benefit. The genial warmth of Queensland is well adapted for the growth of Tobacco, which generally proves a paying crop. There is a feeling that the soil is good enough to produce a first-class variety, and American factories have been started as well as those of home firms. The Government has felt the time was ripe for the employment of an expert instructor in the art of Tobacco culture, and men of capital are now inclined to embark in the undertaking. It appears that cigar Tobacco, which we suppose is "best extra," can be grown as a remunerative crop.

We have heard of an English cigar industry where, at any rate, the outer leaf was guileless in the extreme. We believe it is in Sir John Astley's life that he makes mention of seeing some industrious and ingenious people busily collecting in Bushy Park the fallen and perfect Chestnut leaves, which were to do duty in the manufacture of high-class cigars. We should prefer "pure" Queensland to "home-grown" Bushy.

After tobacco comes coffee, quite in order, and we should hail with

pleasure any new development that would make that fragrant drink cheaper. Really good coffee is costly—that is, in proportion to other drinks of a like nature.

Tea may be weak and void of sugar and cream, and yet very drinkable. Coffee must be of the best, strong, and with flavour developed by pure sugar and rich cream. It is dearer per pound than good tea, and so much more is required to make a palatable drink. It is one of the best and most active of stimulants, and has many other excellent medicinal virtues.

At present not a great deal of Queensland coffee has found its way here. What has come has been much appreciated, showing that the culture and the soil are both right. Government has appointed a qualified instructor. The home consumption is so great that that will have to be satisfied first. Will it be labelled "finest Australian Mocha," or what? We think there is a future before these Australian coffee growers, but we will beg them never even to experimentalise in chicory growing. It is the chicory that gives the indigestion, not the pure wholesome coffee, and it is the chicory that has in so many instances got coffee its bad name. We don't want the coffee of commerce in smart tins or packets, we want the real thing, and if our colony can send it we venture to say it will find a good market.

Still the breakfast table—what would it be without "piggy?" How good on a cold morning is the sizzling of the rashers; how delicious the thin red and white slice from a well cured well boiled ham. We never really tire of pig in its multifarious forms. It comes in for so many dishes, and we are getting a wee bit sick of the Chicago variety. If our own people can send it us at reasonable price and good quality, we can do with it. Articles of daily consumption need only be good to find ready markets.

These cute Australians have taken advantage of the troubles in the Philippines, and have practically got that trade. In 1896 export bacon and ham amounted to £7904, in 1898 to £32,033. Lard, too, is a feature of the trade, though we have no statistics given. That, too, is a need in every household, and a growing need, as every year sees a little increase in the quality of our style of living. Prosperity and good wages are doing this. The table of to-day is a very different thing from the table of twenty years ago. This applies mainly, of course, to the lower and middle classes, and they are numerically the greatest consumers.

The cultivation of Rice, too, has got a firm foothold. Rice and Wheat are always in demand, and will be. The northern part of the province is best adapted for its cultivation, and the cultivation is going by strides. We should like some more information as to the price of land, the chance of opening for our young men, and a few other particulars of a like nature. We have plenty of good farmers in England who begin to think their golden days here are over, and if they or their sons could find openings among congenial surroundings in our home on the other side of the world, many would seize the opportunity.

We want some definite information, a greater entering into details, something about the amount of capital needed, and the status we should occupy there; something about land tenure and the burdens on land, the educational advantages, and a clear statement as to the difficulties that would present themselves to new comers. Perhaps some day we may, through the courtesy of the Agent General, have the means of increasing our knowledge.

WORK ON THE HOME FARM.

We have had a week of mild and windy weather which has done much to dry the land, but it is raining heavily again as we write, so there will be little gained. Wind and more sunshine are wanted. Wheat will soon require rolling; it is showing signs of losing root owing to wireworm, and the sharp frosts before Christmas have left the surface of the land very light.

Young seeds, too, will have to be rolled when possible; the plant is certainly thinner than it was, and it never was a good one. On a recent visit to a neighbouring county we walked over several fields of new seeds without finding one that could be called a decent plant. We have known the time when all such would have been ploughed up, but

the price of grain and labour difficulties make farmers anxious to keep as much land as possible in pasture.

Turnips on sandy soils suffered very much from the frost. We have seen Swedes more than half of which are rotten, and as they never were half a crop what are they worth now? The grower has a large head of sheep, having bought heavily in August, hoping that Turnips would improve; he has now only two weeks' keep for his feeding sheep, and unless he can buy roots, which is very unlikely, will have to sell out at a sacrifice. Early sown Barley has of late done so much better, and realised more than the late, that no doubt many farmers are preparing to drill in February.

The spring tooth cultivator is the best implement to break up the Turnip land for Barley; taken across the ploughing twice it lifts the soil and leaves it light and open, so that the surface water drains away well and the land has a better chance of drying. The old duckfoot drag and chisel-harrow are seldom used nowadays.

Peas for pulling green must soon be sown. The land must be manured at once, if it has not already been done. Peas are a paying crop on warm early soils, but are rather speculative, and it is not wise to grow too many. The Telegraph is the variety now most largely grown in some Pea districts for pulling on a large scale.

AUSTRALIAN EXPERIMENTAL FARMS.

THE importance attached by the various Australian Governments to the encouragement of agriculture, especially by the diffusion of practical knowledge, is shown in the fact that in most of the colonies a Department of Agriculture has been established, the official head of which is a member of the colonial ministry. In New South Wales the necessity for providing the means of technical agricultural education, and establishing a college and model farms in various parts of the colony, became fully recognised, and a site suitable for a central establishment was selected at Ham Commor, near the town of Richmond, in the Hawkesbury district, about thirty-nine miles from Sydney, where an area of about 4000 acres was resumed for the purpose. The buildings and furnishings of the college and farm, now in their seventh year of existence, were completed in January, 1896, and officially opened on the 14th April of the same year. Accommodation is provided for ninety-six resident students, and during 1898 there was a full roll.

Theoretical as well as practical instruction is imparted by experts in every branch of agriculture, and experimental work is carried on with cereal and other crops, fertilisers are tested, analyses of soils are made, and the arts of dishorning and speying cattle, with other veterinary surgical practices, are taught. The live stock attached to the farm and college comprises forty-six horses, fifty-seven bullocks, 151 head of dairy cattle, 140 pigs, and 130 sheep. The operations include the cultivation of Wheat for grain and hay, Maize for grain and silage, Barley for grain and fodder, Oats for grain and hay; Lucerne, Hungarian Millet, Rape, Grapes for fruit and wine, Oranges, various kinds of fruit, Potatoes, Turnips, Mangold Wurtzel, Tobacco, Potatoes, Beans and Peas, Pumpkins, Melons, and different kinds of vegetables. There is an orchard, 30 acres in extent, and a vineyard, 10 acres in extent, and the cultivation of plants for the expression of scent has also been begun. Besides the practice of general dairy farming work, instruction is imparted in cheese making, also in the management and breeding of poultry, in the rearing of bees and the preparation of honey for the market, in the killing and dressing of sheep, in the carpenter's and the blacksmith's work, in the construction of fences, and in various mechanical trades.

There are also experimental farms at Bomen, 304 miles from Sydney, in the Murrumbidgee district; and at Wollongbar, 366 miles from Sydney, in the Richmond River district. The former is near the town of Wagga Wagga, and embraces an area of 2460 acres, of which 1200 acres are in cultivation, 1000 acres being devoted to growing cereals, of which 500 acres are for seed Wheat, the remainder being utilised for oaten hay and malting Barley; 85 acres to fruit trees and Grape Vines; and 80 acres to forage plants, such as Maize, Sorghum, Millet, Barley, Rye, Oats, cow Pea, roots and grasses; while 8 acres are under Olive trees, the remaining portion being taken up by irrigation plots, nursery, and experimental plots. The experimental farm at Bathurst, 145 miles from Sydney, is largely devoted to the cross-breeding of sheep, irrigation, fruit-growing, cereal culture, and general mixed farming. The area of the farm is 596 acres. Another farm is situated at Coolabah, in the dry country, about 424 miles from Sydney, where there are about 200 acres in cultivation.

Under the direction of the Government pathologist, investigations are carried out at the laboratories at the Sydney, Bathurst and Wagga Wagga farms. At a laboratory at Pymble, a few miles from Sydney, the diseases of Citrus plants have formed the subject of special inquiry. Operations at Bathurst are not specially directed to agriculture, but are confined more to the diseases of stock; but at Wagga Wagga, the work of the laboratory is mainly in connection with Wheat and other farm crops. At the chemical laboratory in Sydney special attention has been devoted to the grading of Wheats, the strength of flours, and other matters connected with the improvement of Wheats under Australian conditions.—J. PLUMMER, Sydney, N.S.W.

OUR LETTER BOX.

Measurement of Haystack (G. C. F.).—This stack contains about 270 cubic yards of hay. The finer the quality of the hay the heavier it will weigh, but you will be safe in allowing 23 cubic yards to the ton as an average. If it is good old hay 20 yards would be sufficient for a ton. The stack, therefore, contains 12 to 14 tons, according to solidity.

Jersey Cow with Sore Teats (Admirer).—By all means keep the calf away and remove the milk by hand. There must be great delicacy of the teats, and we should advise (failing a good vet. near) that you apply to a chemist, who will probably be able to give some preparation that would strengthen and harden the teat. If the cow is a valuable one, the "vet." had better be called in. The cow is possibly suffering very much more than you expect. Is the milker gentle and careful? In this instance we should prefer a woman. The matter may soon be put right, but it should have immediate attention.

Sheep (J. P., Bucks).—Yours is rather a difficult question to answer. Among practical farmers we have never seen such a book as you want. The management of sheep would be difficult to teach by means of books; it is a question of experience. However, there are several books published written by clever men who know a good deal of the subject of which they treat. You must understand we do not recommend them from personal knowledge. "Morton's Handbook of the Farm," No. II., 2s. 6d.; "Popular Live Stock Series—Sheep," No. II., 1s. Vinton & Co., Ludgate Circus. "Sheep Raising and Shepherding"—Maldon, 3s. 6d. Upcott Gill, 170, Strand.

MURIATE OF POTASH FOR POTATOES.—In your article on "Potato Experiments in Cheshire" you dwell upon the decrease in the yield apparently caused by applying 2 cwts. of muriate of potash, with other manures, in comparison with the yield from 1 cwt., and you sum up against that form of potash. But in 1898, as well as in 1899, at Holmes Chapel 1 cwt. of muriate of potash beat 2 cwts. of sulphate of potash, or 4 cwts. to 5 cwts. of kainit. It is probable that the doubling of the muriate retarded the maturity of the Potatoes; but nothing is more common in experiments with artificial manures than a decrease in a crop when an excessive quantity of a manure highly beneficial in moderate quantity is applied.—W. E. B.

STABLE MANURE FOR WHEAT.—The practice of drawing out stable manure to be spread on stubble ground and ploughed under for Wheat is much less common than it used to be. Farmers have learned that if manure is ploughed under in the autumn it does very little good to the Wheat crop, and is often absolutely injurious, as it makes the soil above it hold much more moisture than it otherwise would. The soil beneath the seed bed of 2 inches should be left as firm as possible in autumn for any winter grain. It may, however, pay to use it as a top-dressing to make a large Clover growth. For the Wheat crop itself 200 lbs. of phosphate per acre drilled with the seed is better than double that value of stable manure.—("American Cultivator.")

DRAINING.—When setting about draining the first requisite is to haul the pipes, and as land which has to be drained is as a matter of course wet, there is sometimes difficulty in getting the pipes on. Therefore when opportunity offers through frost or a spell of dry weather the hauling should go on with despatch. There are certain clay lands that become sterile if the excess of water is not drawn off, and here draining should be done with promptitude, thoroughness, and with really good hard burnt pipes. Pipes properly burnt will be tolerably sound in the ground for half a century, while middling burnt ones crumble down in a year or two. As to depth of draining, it is the most important matter of all. The more clayey the soil the less porous it is, hence the less capable of draining off water. Here from 24 inches to 28 inches deep is sufficient, but on more open ground, where springs from beneath give the excess of water, from 30 inches to 36 inches is not too deep. It is surface water mostly that soddens the ground on clayey soils.—("Rural World.")

LET THE HARNESS FIT.—All those who have horses under their care should in our changeable climate—indeed, at all times—see that the harness fits the animal to which it is applied. It is necessary that the fit be a good one at all times, but in cold weather the hide of the horse will put up with a good deal of chafing without becoming sore, whereas in hot weather it frays very easily. Then in changeable temperature the sweat dries, the salty exudations become dry and encrusted on the edges of the galls produced, and sores that are obstinate enough about healing are the result. Collars and saddles get very wet with sweat, and if both they and the skin on which they rest are not properly attended to trouble quickly ensues. Crupper galls are not uncommon, and a throat latch that does not fit well often makes a nasty sore. It is so very easy to make harness fit well, down to the least important strap, that there is no excuse for any part of the gear chafing the horse. When one sees a horse's shoulders all raw, one may make up his mind that the groom in charge is a slovenly fellow that merits his discharge richly, and so with all harness galls. Owing to faulty formation sometimes it is very hard to keep a horse's shoulders from getting galled. In this case the only thing to be done is to have a maker construct a collar of special pattern.—("Rural World.")

BARR'S SEED GUIDE NOW READY (FREE).

BARR'S SEEDS

OF FINEST SELECTED STRAINS AND TESTED GROWTH

THE BEST SEEDS IN THE WORLD for securing a supply of Vegetables "the year round," and for keeping the Flower Garden always gay, and with abundance of Flowers to cut for vases and bouquets; also Seeds of Plants for Greenhouse decoration summer and winter.

BARR'S SEED GUIDE contains a select List of the best Vegetables and the most beautiful Flowers for Garden and Greenhouse. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors, SENT FREE ON APPLICATION.

BARR'S 21/- COLLECTION OF VEGETABLE SEEDS contains a liberal assortment of the following useful Vegetables: Beans (Broad and French Beans), Beet, Borecole, Broccoli, Brussels Sprouts, Cabbage, Capsicum, Carrot, Cauliflower, Celery, Colewort, Corn Salad, Cucumber, Cress, Endive, Herbs, Leek, Lettuce, Melon, Mustard, Onions, Parsley, Parsnips, Peas, Radish, Salsify, Savoy Cabbage, Scorzoneria, Spinach, Tomato, Turnip, and Vegetable Marrow.

OTHER COLLECTIONS OF BARR'S VEGETABLE SEEDS, 5/6, 7/6, 12/6, 42/-, 63/-, and 105/-.

These Collections sent carriage paid on receipt of remittance. Full particulars on application.

BARR'S CHOICE FLOWER SEEDS.—The "Seed Guide" contains a Select List of all the most beautiful Annuals and Perennials. Special Collections for all purposes, and many Sterling Novelties.

All Seeds sent Carriage Paid on receipt of remittance.

BARR & SONS,
12 & 13, King Street, Covent Garden, London.
Nurseries: LONG DITTON, SURREY

CLIBRAN'S' CHRYSANTHEMUM CATALOGUE,

For descriptions of each variety, also of

NOVELTIES FOR 1900.

NOTE.—Post Free and Ready Now!

WM. CLIBRAN & SON, ALTRINGHAM & MANCHESTER.

ALL WHO WISH GRAND RESULTS should use THOMSON'S IMPROVED VINE, PLANT and VEGETABLE MANURE. This valuable Manure is yearly growing in public favour. Can be had of all Nursery and Seedsmen, or direct from the makers, WM. THOMSON and SONS, Ltd., Tweed Vineyard, Clovenfords, Galashiels, N.B. Price Lists and Testimonials on Application. 1 cwt. and upwards Carriage Paid to all stations in Britain and Ireland. London Agent—Mr. J. GEORGE, 14, Redgrave Road, Putney. Agent for Channel Islands—Mr. J. H. PARSONS, Market Place, Guernsey. Also THOMSON'S SPECIAL CHRYSANTHEMUM MANURE. 1/2 cwt. Carriage Paid to all Stations in Britain and Ireland.

COTTAGE GARDENING; being an Essay to which the Royal Horticultural Society awarded Mr. W. EGERTON HUBBARD'S Prize, February 16th, 1870. By E. W. BADGER. Third Edition. Price 3d.; post free, 3 1/2d. Office: 12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—HIRST, BROOKE & HIRST, Ltd., Leeds

HEATING APPARATUS for Greenhouses and other Buildings. Catalogue free of all kinds of Hot Water Pipes, Wrought and Cast Iron Boilers, Radiators, Cisterns, Pumps, Baths, &c.—JONES & ATTWOOD, Stourbridge.

GREENHOUSES from £3 5/-; VINERIES, CONSERVATORIES, FRAMES, SUMMER HOUSES, &c. Illustrated List Free. Makers to H.M. THE QUEEN and H.R.H. THE PRINCE OF WALES.

E. B. HAWTHORN & CO., Ltd., London Works, READING. (Name Paper.)

ECKFORD'S SPECIALITIES

ONLY GENUINE DIRECT FROM WEM

AWARDED 46 GOLD & SILVER MEDALS

SWEET PEAS!

The BIGGEST SUCCESS of all is ECKFORD'S GIANT SWEET PEAS. The PURITY and STAMINA of these Home Grown Stocks are so conserved by SPECIAL METHODS of CULTURE that the seeds are PHENOMENAL for UNRIVALLED STRENGTH and VITALITY, and with proper cultivation, give the HIGHEST POSSIBLE MAXIMA of results!

Prizes offered in 1900 alone exceed £40! Collections from 1/6 upwards.

(See particulars in Catalogue.)

See beautiful plate of SWEET PEA NOVELTIES for 1900, sent gratis with each Catalogue.

CULINARY PEAS!

ECKFORD'S CULINARY PEAS are positively UNRIVALLED by any on the Market for FLAVOUR and CROPPING CAPACITY! ENORMOUS YIELDS under favourable conditions. Collections for 5 months continuous supply (See page 2 Catalogue.)

PURE VEGETABLE SEEDS!

Results from ALL QUARTERS prove that ECKFORD'S SEED, for PURITY, VIGOUR, and YIELD, are the CHEAPEST and BEST ever offered to the Public! Collection for 12 months supply, 12/6, 21/-, 42/-, 63/-, 105/-, all carriage paid. Other Collections, 2/9, 5/-, 7/6, post free.

CINERARIA (SILVER MEDAL STRAIN). Giant Flowers, splendid habit, unequalled!
PRIMULA SINENSIS. Unique Novelties and Grand Collection of named varieties
PANSY. World-famed strain of FANCY SHOW, PEACOCK, and FLAKED VARIETIES!
VERBENA. RENOWNED RACE of EXCEPTIONAL MERIT!

Don't buy till you have seen it! **ILLUSTRATED Catalogue & Cultural Notes POST FREE!** If you love Gardening send for one!

HENRY ECKFORD,
SEED CROWER, WEM, SHROPSHIRE.

ONION—NE PLUS ULTRA.

AWARD OF MERIT, R.H.S.

The Finest and Largest Onion for Exhibition Purposes. 2/6 PER PACKET.

Special Prizes for the best 12 Onions will be given at the Hemel Hempstead Horticultural Society's Show.

LEWIS DUNBAR, SEEDSMAN, HEMEL HEMPSTEAD

WEST'S PATENT GARDEN SPECIALITIES.

WEST'S PATENT

Vapourising Fumigator

Best and Cheapest, for being made of brass and zinc will last for years. The stove only requires a little spirit to saturate the asbestos, so may be used thousands of times without wick or further trouble than filling it. Price 6d. complete to vaporise up to 2500 cubic ft.

"WEST'S EXTRACT OF NICOTINE" is guaranteed pure Nicotine and is even cheaper than the compounds that are only chemical substitutes for Nicotine (compare prices), 7d. per air-tight sealed bottle of 1000 cubic ft.

"SUNPROOF" SHADING in 6d. lb. tins ready for use, to be mixed with cold water. Guaranteed to be perfect in all respects and the cheapest shading that can be made.

For particulars of West's patent "Ivorine" Plant Labels, Soft Metal Tree Fasteners, S.M. Clips, Wall Nails, Plant Stake Grips, Plant Pot Cocks, Insecticides, Fertilisers, Canes, Sticks, and ALL GARDEN SUNDRIES of every description see Illustrated Catalogue, post free.

Samples free, postage for samples and goods extra. All goods made on the premises by C. E. West, so send direct to the Manufacturers.

Gratis "Orchid Culture," 3rd Edition, postage 2d.

Gives full particulars of the cultivation of Orchids. THE LEEDS ORCHID COMPANY, ROUNDHAY, LEEDS

Journal of Horticulture.

THE JOURNAL OF HORTICULTURE can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 12, Mitre Court Chambers, Fleet Street, London.

CUTTINGS.

WHAT was lately advanced concerning seedlings and the advantage derived by the plant in a mature stage of growth from its treatment in infancy, applies with equal force to plants propagated by other methods. It is a sound rule which says that a plant, by whatever method it is propagated, should be grown without check in its earlier stages. Gardening is, of course, largely made up of compromises, and it is not possible to carry every rule to its legitimate conclusion.

One might allude in this connection to Zonal Pelargoniums rooted in autumn and preserved in a quiescent state until spring, or to Chrysanthemums rooted in winter and then transferred to cold frames where the environments are necessarily not stimulating to vegetation. But in the latter case it must be remembered that the Chrysanthemum is practically hardy, and though little growth may be made in January or in February there is no reason why the progress should not be of a satisfactory nature. With the Pelargoniums it is different, and as a matter of fact the check to growth is of so pronounced a nature that I have discontinued propagating these in autumn for blooming the year succeeding, finding as I do that better plants are produced from spring-rooted cuttings which are permitted to experience no check to growth. At the same time, autumn propagation will in not a few cases be the only method possible.

Attention to this matter is under the present day system of high pressure of more importance than formerly. We now must have plants, the greater number of not more than annual duration, Crotons, Carnations, Pelargoniums, Marguerites, Solanums, and such like, and any loss of time in their production means dissatisfaction at least. It is an indisputable fact that loss occurs not during summer or autumn, but while the plants are yet small. Apart altogether from check to growth, which I am afraid can never be quite overcome, if plants either as rooted cuttings or in a more advanced stage are permitted to stand unpotted for a week or two after reaching a proper condition for this operation the loss is irremediable.

There are two methods of insuring against this waste—the former being to repot young stock rapidly till the proper size of pot has been reached, or to place into the final size at once. For not a few rapid-growing plants—*e.g.*, Marguerites, Salvias, and Eupatoriums—it is indeed the preferable method to place well rooted cuttings directly into the flowering size; the only risk is in over-watering during the earlier weeks of the plant's life in the pot. That avoided, the results are certain to be equal, and probably better, than by the frequent repotting system, because there is no check to growth when once the little plant recovers from its one move. The practice in producing large plants, to be most successful, must also be carried out on these lines. The handiest Fuchsias, Ferns, and many other plants are produced by a continuous growth. An old friend of my own, at a period when Malmaison Carnations were hardly known, used to annually bloom a few large plants in every way perfect, and the method he pursued was to grow them without check, at the same time permitting no flower to appear till the desired dimensions had been obtained in the plants. A gardener at Clapham, about a quarter of a century ago, produced huge Crotons in a comparatively short time. If my recollection is not at fault, plants he showed me, 6 or 7 feet high, were grown in twenty months from cuttings, and his secret was unchecked growth.

One may admit all this to be true, and yet be in a position that renders it impossible to take opportunity by the forelock. But even then something may be done that, if not so satisfactory as the necessary work at the proper moment, is at least helpful in lessening the mischief. I refer to aiding young plants by means of manure, and preferably with manure of a chemical nature. There need be no hesitation in applying slight periodical dressings to young plants that have to remain in small pots beyond the time they ought to be removed. It does not stop the check to growth, but it hinders it from becoming disastrous, and preserves foliage and roots in an abnormally healthy condition, and capable of taking advantage of the delayed transference whenever it is provided.—B.

REMINISCENCES OF AN OLD FLORIST.—No. 4.

ONE of my earliest reminiscences of nursery gardens was that of Mr. Charles Turner of Slough. I paid him a visit some few years before I came to reside in England. He was then in a small place called Chalvey, near Slough; and had only a few frames in which he cultivated Pansies and Pinks. He was the same genial companion he always remained, being the very prince of florists, so that one need not at all wonder at his onward progress, and at the splendid and unique establishment which he formed at Slough. Nothing in the way of florists' flowers came amiss to him, though he did not confine himself to these. Nobody, I think, ever grew Carnations and Picotees as he did, while for years his collection of Auriculas was the only one near the metropolis worthy of the name. In his time, too, he had a splendid collection of florist's Tulips, and his beds of these were a sight worth going to see. There were many collections at that time of this grand flower in the neighbourhood of London, and amongst them may be mentioned that of Mr. Groom of Walworth. There were many bulbs in his catalogue which were priced from £20 to £50 each. I believe Mr. Turner was induced to take up their culture, as well as that of the Auricula, by his friend, Mr. John Edwards, and the culture of the Tulip was carried out by him enthusiastically for many years. At last, however, he was forced to give them up. "It would pay me better," he has often said to me, "to grow Lettuces." The same falling off of the taste for the Tulip has continued for many years, and now there are no collections I think about London.

But Mr. Turner's attention was not merely confined to florist flowers. Whatever he took in hand he did well and succeeded with. Many will remember the magnificent plants of *Azalea indica* which he used to exhibit at the metropolitan shows at the Crystal Palace and Botanic Gardens, as well as the grand pot Roses. The taste for these monsters has gone out, but they were marvels of cultural skill. The same may be said of his Pelargoniums, both Show and Fancy.

The plants were 3 and 4 feet through, and every single bloom was in the highest state of perfection. I need hardly say that it required the utmost cultural skill to produce these effects. In the Fancy Pelargonium, the more difficult of the two to grow, he was an adept, and he and Mr. Bailey of Shardloes were rivals between whom it was most difficult to adjudicate.

Year after year he used to put into commerce the new varieties raised by Mr. Garth of Farnham and Mr. Foster of Clewer Manor, and what a furore they created. I have seen a string of carriages waiting at Catleugh's shop at Hans Street, Chelsea, and ladies of title waiting for their plants for some of which they had paid £5 5s. apiece. I remember the bringing out of Garth's Joan of Arc, which it was considered at the time could never be surpassed. It was brilliant in colour, but deficient in shape, and in a few years went out of cultivation. Many years after this I paid a visit to Mr. Hoyle of Reading, and he showed me a very interesting series of blooms of flowers of his own raising, illustrating the immense strides which from time to time had been made, until at last such perfection of outline, such brilliancy of colour and softness of tints had been arrived at, that no perceptible change could be seen in the flowers of successive years, and so they had to take a back seat. I have always deplored this, for I do not think there was a more beautiful and refined class of flowers than these Pelargoniums.

Amongst the accomplishments of Mr. Turner was his taste in arrangement. I have seen him coming in front of a stage of "Geraniums" which his men had put up, shake his head at their arrangement, and in a few minutes he would so alter them that the collection looked 50 per cent. better. So I have also seen him look at a box of cut Roses belonging to someone else and say, "What a duffer that man is; I should like to have five minutes at that box." I have no doubt that if he had had he would have altered it completely.

There were two friends of Charles Turner whom I used often to meet at his house, John Spencer, of Bowood, and John Standish, of Bagshot, of the latter of these I shall have more to say by-and-by. The former was gardener and steward to the Marquis of Lansdowne, and best known to the horticultural world as a successful grower of Grapes; he was the raiser of Bowood Muscat, a double plate figure of which was given in the "Florist." It was a seedling from that best of all white Grapes, Muscat of Alexandria, which it closely resembles, but Dr. Hogg in his "Fruit Manual," states that it sets better and is more prolific. One thing connected with Charles Turner many will recollect, his splendid tenor voice, which many used to say equalled that of Sims Reeves. It is pleasant to find the old establishment carried on by his sons, and not, as in so many cases, passing into the hands of others. For many years Mr. Turner was a most successful grower of Dahlias, and he and John Keynes, of Salisbury, used to run one another very closely, not only in the exhibition of varieties, but also in the production of seedlings. When Roses came so much in vogue he was also a successful exhibitor in them, though he did not obtain the high position in them that he did in the former flower. But whatever place he occupied he was never found storming about defeat or exulting over success, and other exhibitors were always glad to find him competing with them. He has passed away, and the place that knew him knows him no more, but his name remains connected with many good flowers in the various sections in which he used to exhibit.—D., Deal.

HAMAMELIS ARBOREA.

THIS is undoubtedly the best of the Witch Hazels, and should be grown by everyone who has space for it, as it makes a warm patch of colour outdoors when flowers in the open are very scarce. It forms a tall shrub or small tree about 12 or 15 feet high, with many large, rather flat branches, which are covered in January and February with the peculiarly shaped yellow flowers.

It will thrive in any fairly good rather light soil, and is not particular as to situation, provided it is not too shaded; but it should, being a deciduous plant, and consequently leafless when in flower, be planted against a good background of evergreens, which will serve to throw its bright flowers into strong relief against their darker foliage. The flowers are borne on short spurs, in clusters of two or three, and consist of four strap-shaped, crinkled, deep yellow petals, each a little over half an inch in length, which are inserted in a small claret-coloured calyx, consisting of four reflexed sepals.

It is a first-rate plant for a large bed, where six or eight together will make a grand display in the winter, and if the surface of the bed is planted with Snowdrops or Chionodoxas the effect is much enhanced. It is a native of Japan. A good companion to the above is *H. japonica-zuccariniana*, also of Japanese origin, and having flowers of a pale lemon-yellow or straw colour. It thrives under the same conditions, grows about the same size, and flowers at the same time.—C.

ODONTOGLOSSUM CRISPUM FRANZ MAZAREEL.

"YOUNG Orchid Grower" asks if we can say when and by whom *Odontoglossum crispum* Franz Mazareel was shown before the Royal Horticultural Society. The date of exhibition was November 13th, 1894, and the exhibitors were Messrs. Vervae & Co., Mont St. Amand, Ghent. The variety was described in the *Journal of Horticulture* at the time as "having flowers of the ordinary size, but noteworthy for the wonderful colouring." The sepals and petals are white covered with red blotches, the lip being lemon yellow. It is one of the best varieties of this popular Orchid we have seen, and worthy of the first class certificate awarded for it." The illustration (fig. 26) will also be of interest to our correspondent.

ARRANGING ORCHIDS.

PERSONS interested in Orchid culture, and who have frequent opportunities for inspecting some of the finest collections in the country, must often have been struck by the fact that little or no effort is made to utilise the abundant material so as to create beautiful displays. One finds in the majority of places that the *Odontoglossums*, the *Cattleyas*, and so on are almost invariably kept in their respective structures, and beautiful as some of these undoubtedly are, a combination would be infinitely more so. The reason for this practice is not far to seek. Those who cultivate Orchids are largely specialists, and many of them have a rooted objection to heterogeneous mixtures, preferring to retain the several kinds *en masse*. If the matter be probed still further it will probably be to learn that the temperature that suits one kind does not suit another, and that the plan of making a real show house is not feasible, as the plants would inevitably suffer.

To a degree this may be so, but that it is an insurmountable objection is by no means so obvious. I have in my travels found one or two Orchid establishments where the system of maintaining, as far as possible, at least one structure in a constant state of beauty with miscellaneous kinds, and I have never learnt that the plants have suffered from the practice. That there is danger will be admitted by everyone, but the same may be said of our conservatories, which have, whether suitable or not, to accommodate all kinds of plants. As in the latter case so in the former. It merely resolves itself into a question of attention, and certainly no one would suppose that the enthusiastic Orchid grower would neglect his plants simply because their peerless beauties had been concentrated in one structure; rather the reverse, most people would say.

If the plants had to continue constantly in one house disaster to many and probably the whole of the occupants would soon follow. Such, however, is not the case. I would plead now for what might be termed an Orchid show-house, where each plant as it approached its most perfect beauty might find position, and whence it would be removed directly its charms began to wane. This would not necessitate a very long sojourn in an uncongenial temperature, and visitors who were not orchidists would have the pleasure of their inspection much increased by the practice. The enthusiast, as everyone knows, finds equal interest in the plants whether they are in flower or not, but the outsider, who has not been educated up to such a state, finds the steady progress through a dozen houses, each containing about a dozen flowers, the reverse of exhilarating. He sees little beauty in the pseudo-bulbs and leaves, though these may be in the best possible health.

To my mind it is not possible to make an equally beautiful display with any other plants as can be effected with Orchids, Ferns, and some small Palms. There are to be found in the *Cypripediums*, *Dendrobiums*, *Phalaenopsis*, *Cymbidiums*, *Odontoglossums*, *Lycastes*, *Cattleyas*, *Laelias*, *Oncidiums*, and the several others, types of such exquisitely delicate beauty as to entrance everyone who inspects them. And when a number of these is concentrated in one suitable place, and the soft greenery of Ferns and Palms skilfully utilised, the observer has such a feast as to send him away with a mind full of what has been seen, and which has made such an impression as is little likely to be effaced. I wish some of the Orchid loving readers of our Journal would give us the benefit of their ideas on this subject.

—TRAVELLER.

[As illustrative of a portion of our correspondent's text we give (fig. 30, page 119), a photographic illustration of a show house of Orchids, the beauty of which is certainly an argument in favour of the extension to the system "Traveller" advocates.]

THE WANDERINGS OF MR. PETER BARR, V.M.H.

NEW YORK being left behind, I made for Wyoming State to visit the wonderful Yellowstone Park. The tour of this is made by carriage, which takes travellers to all the interesting geysers. This park has been put aside as a reservation to preserve its natural beauty, the wonderful geysers, and the fauna. The buffalo which used to be so numerous all around that a drove of them took days to pass a certain point, have all been killed off, and a small herd in the park of some 100 yearly keep dwindling, as they are shot immediately they get out of the park. The hide and head now realise a considerable sum of money. A large body of soldiers are kept on police duty in the park summer and winter to guard the geysers and the wild animals. In an evening visitors who have a little nerve go out and watch the bears looking after the refuse from the hotels where the visitors put up in making the round of the park.

After the park, I made for Salt Lake City, and called on Bishop Romney, who has four wives. He got out his carriage with one of his wives, and drove me all about the town. I spent one day with Mrs. Emmeline Blanche Wells, who had been the sixth wife of Mr. Wells, one of Brigham Young's principal advisers.

After Salt Lake City I went through Leadville, Glenwood Springs, Colorado Spring, and other places, to Kansas City. I visited St. Louis, and at Shaw's Botanic Garden (Missouri Botanic Garden) I found Mr. James Gurney, the head gardener, who claims to have first flowered the

FIG. 26.—ODONTOGLOSSUM CRISPUM FRANZ MAZAREEL.

Victoria Regia at Regent's Park Botanic Gardens. Mr. Trelease, a Cornishman, I think, is the Botanical Professor. Here is the finest pre-Linnean library in America (Boston, Mass., has the finest horticultural library in America, perhaps the world), and it is not unlikely St. Louis has the finest pre-Linnean library outside the British Museum.

At Indianapolis, when sauntering up North Meridian Street admiring the fine homes and the well-grown trees, wondering what their age was (fifty years old I found afterwards), and wondering how long it would take them to die, as the City Board of Works had laid a fine cement street and cement footpath, and left no provision for water getting at the roots, I was startled by a girl's voice at my side. "Are you Mr. Peter Barr of London?" Mechanically I answered, "Yes." Then she said, "My mother wants to see you." So I turned into one of the finest homes in the fine avenue, and the lady was waiting to give me a welcome. I had never seen her and she had never seen me; but two years before I had met her husband in Copenhagen. She said, "He has gone to see the young Queen of Holland crowned, and I want to do in his absence what would have been done had he been here. You will dine with us to-night?" I had to pause and ask, "But how came you to recognise me?" This was answered by, "Oh, we have your photo, and knowing you would visit America and seeing you coming up the street as I was sitting in the verandah, I said, 'There is Peter Barr!' and I sent Elizabeth after you." I accepted the invitation. After dinner the horses were put in the carriage, and drove to the railway station, and then Mrs. Pierce asked me what baggage I had, and a porter was called, the traps were collected and put in the carriage, then to the hotel, got my hand-bag, after this to the newspaper offices, and I was duly heralded as a visitor at the house of Mrs. Elizabeth Pierce. Here I was detained some eight days. First the parkman was sent for, and he drove me two days about the parks in process of making and the finished parks. After this came the newspaper men to know what I thought of Indianapolis, its streets and parks. I condemned the felling of the trees in the streets, told them of the fine possibilities of their parks, and advised that the parkman

should have a free hand, and so on. Then in Mrs. Pierce's carriage I drove about to see the industries, also into the country to see what was to be seen, and had introductions to all and sundry.

After this happy experience I spent some days in Chicago under the care of Mr. Michael Barker of the "American Florist," Mr. Grand of the "Florists' Review," Mr. Vaughan the great Western seedsman, and of course the parks had all to be gone over with one of the engineers—Mr. Edgar Sanders, a well-known figure in Chicago. He brought me some literature touching Barr, the nurseryman of Balls Pond, the first man, or his partner, to send a collector to China to bring home the Chrysanthemums; he told me how he failed and came and settled in Chicago, first as a farmer and then as a nurseryman. Visited Graceland Cemetery, where you can plant a tree to mark your freehold or put a border or an ornamental building that will fall in with landscape effect, but no headstones or other disfigurement. Chicago, when the parks system is finished, I suppose, will boast of the finest town parks in the world. I made some suggestions condemning the floral elephants, monkeys, and other monstrosities. All was to be reformed as the public taste could be led from the vulgar to the sublime.

Milwaukee was my next place. Here Mr. Currie, the seedsman, got the wheels of his buggy greased, and I was hurled about the parks. I had hardly settled myself when a lady reporter called to ask my opinion of the parks. I said they were all too small, but well laid out originally, but some evil genius was at work spoiling the whole affair. This was nuts and honey to the lady. I gave her a few points, such as red Alternanthera in wavy lines in the grass, and asked her if a lady would adorn herself so, adding the same effect could be produced with pickled cabbage. Next morning a stinging article appeared, and the following night she came for more copy, and I condemned the filling up of the ravines and the great terra cotta pillars to bridges which should have been quiet and unobtrusive. The following day came a hot note from the Chairman of Parks to justify his work; but it was his death blow. The City of Milwaukee was tired of the man; he had usurped all the power and did as he pleased, so the next Mayor shelved him.

At Cincinnati I was met at the station by Dr. Holmes and his wife, and dined with the parkman and the cemetery superintendent, both fine men. The cemetery is charming, although too full of obelisks, but the trees save the bad effect. The parks are not rich, but great things are in contemplation. There is at present great competition with the towns of the U.S.A. for parks, large and small, to meet all classes and grades of society.

NOTES ON ALPINE FLOWERS.

SEMPERVIVUM ARACHNOIDEUM.

A CONSIDERABLE time ago the writer took occasion to speak in favour of the Houseleek known in gardens as *S. Laggeri*, but which botanists now rank as a variety of *Sempervivum arachnoideum*. The latter, which I suppose we must take as the type, is in its own way quite as pretty as the larger variety *Laggeri*. The cobweb-like tomentum, which makes the larger variety so attractive, is as well marked in the type, and when a number of rosettes have formed themselves into a dense mass they are effective indeed, especially in dry weather, when the "cobweb" shows up quite silk-like. The best place to grow the Cobweb Houseleek is on the side of a wall, or in crevices of rockwork so planted that it is in a vertical position. Grown thus the rain does not lie in the rosettes, and the danger of decay from excessive moisture is warded off. It is perfectly hardy as regards frost, but wet in winter is not only injurious to it at that season, but lessens its beauty in summer. The flowers, which come in June or July, are in a cluster at the top of a long, thick, fleshy stem clothed with thick leaves. When the rosette flowers it dies, so that I always advise those who can only secure a single rosette at first to take one which does not show any sign of flowering. *S. arachnoideum* likes a soil composed of sandy peat, but I always add some old mortar or broken limestone to the compost, together with a little thoroughly decayed cow manure.

LINARIA ORIGANIFOLIA.

While the Marjoram-leaved Toad Flax is generally ranked as a perennial, the writer has found that it cannot be depended on to survive every winter, and that it is generally safer to treat it as a biennial, and to raise it from seeds, or to propagate a reserve stock from cuttings. It comes from the South of Europe, so that this precaution is not unreasonable, although some gardens are so situated that the owners consider it quite hardy. It is not improbable that it is kept up by self-sown seedlings in these gardens, as is the case in that of the writer. It grows from 6 to 10 inches in height, and produces a number of small, bluish flowers with a yellow throat. These bloom over several months, generally coming into flower in June, and continuing until September. It likes a loamy soil with the addition of a little peat.

LINNEA BOREALIS.

Any plant which has been selected to bear the name of the great botanist to whom science owes so much deserves our notice. That the *Linnaea* received its name with the sanction of Linnaeus himself, and was chosen to be typical of his early career, ought to make this little plant doubly precious, most of those acquainted with the life of the

botanist will agree. Linnaeus himself spoke of it as—"an humble, despised, and neglected Lapland plant, flowering at an early age, like the person whose name it bears." Its generic name is, however, far from being its only recommendation, for it is one of the neatest and most charming of the dwarfed beauties which are so dear to every admirer of alpine plants. Its attractive small leaves and its twin pinkish blossoms depending gracefully from the stalks make it much admired. It is widely spread over the northern regions. It is often far from successful in rock gardens, but is not difficult to grow if its wants are studied. It likes a rather shady place in a well-drained but moist nook in the rockery, where it has sufficient space to spread by means of its creeping branches. One would hardly think from its general appearance that the *Linnaea* is related to the Honeysuckle and other plants of the same order; yet this is the case. Division is the only method of increasing it with which I am acquainted.

SEDUM REFLEXUM.

Some readers will possibly find fault with me for writing in these notes about a plant which the advanced grower of alpine plants is disposed to despise. But this Stonecrop has its uses on large rockwork or in carpeting the ground where some of the rockery shrubs are planted. It is always fresh with its trails of pointed leaves, and its yellow flowers, though rather coarse, make a bright feature even in the luxuriance of the feast of June and July flowers. It practically requires no cultivation, except, it may be, in restraining its tendency to spread too rapidly. Even a single branch stuck in the ground is almost certain to grow. It is of evergreen habit—ALPINUS.

JUSTICIA FLAVICOMA.

I WAS induced to take up the cultivation of this plant with the hope of making it useful during the months of September and October, but in this I have so far failed. I thought that it could be so managed as in the case of *Justicia carnea*; it appears, however, to be predisposed to flowering at this season instead. It is an easy plant to grow in an ordinary stove, and may be treated in a similar manner to the *Poinsettia* by rooting a fresh stock every spring. It propagates readily from the shoots as ordinary cuttings or from eyes. Large pots are not necessary—nothing beyond a 6-inch pot is in any sense desirable. Dwarf plants may be had by an occasional pinching, and thus treated it would not be a difficult matter to have plants from 12 to 18 inches high with a dozen or more spikes upon them. For this season in association with *Eranthemum pulchellum*, with its deep blue flowers, it is an admirable plant. In "Nicholson's Dictionary of Gardening" it will be found under *Schaneria flavicoma*.—JAS. HUDSON, *Gunnorsbury House, Acton*.

Justicia flavicoma (fig. 27) is known also as *J. calytricha*, but according to the "Index Kewensis" the correct name is *Schaneria calycotricha*. The examples exhibited by Mr. Hudson at the meeting of the Royal Horticultural Society held in the Drill Hall on January 23rd were greatly admired by those present. It is one of the most useful yellow flowering plants in cultivation for purposes of decoration during the winter and spring. If pushed forward in the autumn in a temperature of 60° it can be had in bloom early in January, and will continue flowering until May in any structure where the temperature does not fall below 45°. The plants should not be thrown away after the first flowers fade, for they quickly come into flower again, and are more beautiful than is the case at first. Those who have not the temperature named may grow the plant successfully if they can command a night temperature of 45° to 50° during the winter.

Plants for decoration in 5 and 6-inch pots should be raised from cuttings annually. These are quickly produced if a few plants are pushed forward in brisk heat after flowering. The cuttings formed of young growths root freely in sandy soil, either singly in small pots, or a number may be placed together, well watered, and then covered with a bell-glass, hand-light, or be placed in a propagating frame. If inserted together they must be potted singly directly they are rooted. As soon as they are established in 3-inch pots the points of the plants may be removed to induce them to branch. The plants are not pinched more than twice, and are placed in their largest pots as soon as a good number of roots has been made.

When well established they may be grown in cold frames through the summer months, closing the frame early in the afternoon. By the middle of September the plants will be dwarf and sturdy, not more than 1 foot high, and should be given a light position in some structure where the temperature named can be maintained. These plants do well in a compost of fibrous loam three parts, the other part being composed of leaf mould and manure, about one-seventh of the latter with the addition of a liberal quantity of sand.

PRUNING.

UNQUESTIONABLY many fruit trees have been greatly benefited by the pruning to which they have been subjected during winter; but, on the other hand, others have about as certainly been rendered less fruitful by the free and ill-considered application of the knife to their branches. Pruning must be conducted in accordance not only with the habits of the trees, but also in accordance with the nature of the soil in which they are growing. It has been said that if summer-pruning is intelligently performed that little remains to be done in winter, which is true; and it is equally true that the pruning of trees in summer

'opening out of their centres' is seldom satisfactory. The time for benefiting the trees by exposing the branches in their interior has passed if the pruning has been deferred until long after those branches have become leafless and spurless. Such wood cannot be made productive, and the only result of such pruning is a mass of young sappy shoots growing where the sun cannot shine on their leaves or the air circulate freely to render the wood fruitful.

THINNING THE BRANCHES.

As a rule, standard and bush fruit trees which have been permitted to grow in a natural and semi-wild state had better remain so, and

FIG. 27.—JUSTICIA FLAVICOMA.

is more effectual in the production of fruit than cutting them severely in winter. Yet although this has been demonstrated over and over again and the fact became public property many years ago, there remains still a considerable amount of pruning to be done during the winter months.

NEGLECTED TREES.

Not infrequently we find that trees have been neglected for one or more years, and usually the longer they have been neglected the more severe is the pruning to which they are subjected, as if to compensate for past neglect. That is a common practice, and it may be added a common mistake. The extreme mutilation of trees during the winter is not promotive of fruitfulness. If the trees have been long neglected, be they Apple trees or Gooseberry bushes, the sudden and violent

continue bearing on the extremities of their branches until superior fruit can be obtained from young and better managed trees. If any pruning is done to such trees it should be limited to a moderate thinning-out of the branches, severing them as close as possible to the main stems; for if the branches are simply shortened the growth in two years will be more crowded than ever, and the result will be more leaves but less fruit than before. The excessive pruning to which young trees are often subjected has been frequently alluded to, and evidence adduced to show that a more natural system of growth possesses advantages where large crops of fruit are the main object in view. By rigid summer-pinching and root-pruning a tree can be brought into a bearing state and be made to form a mass of fruit spurs before it has attained a height of 3 feet. But of what real use is that tree? In certain

positions such trees are ornamental, but the most that can be said about them is that they are cultivated toys—gardeners' and amateurs' playthings. For practical usefulness, and for yielding a substantial supply of fruit, they are of small value in comparison with trees that have not been crippled by the "skill" of man. Trees managed on the violent restrictive principle alluded to are at ten years of age of no greater value than they were when at five or six years old, and at twenty years old what are they? Answer, Dead or dying. If owners of gardens desire to have the Japanese style carried out because of a certain amount of pleasure it gives, they have of course a perfect right to that form of gratification; but do not let the system be mis-called a "profitable mode of fruit culture," because hundreds of gardeners know that it is not profitable.

SYMMETRY *versus* FRUIT.

Another plan of managing dwarf trees that is perhaps more common than that above noticed is only a few degrees less profitable. It is somewhat as follows:—Dwarf trees are purchased that are intended to be grown on the summer-pinching principle, but not on the root-pruning system. They are intended to be moderately dwarf and healthy, not extremely dwarf and unhealthy. The idea is good, but is not always carried out properly. So far as the roots are concerned the prescribed rule of culture is adhered to, for they are left unchecked, but the summer-pinching is not thorough or persistently conducted. For the first year or two, when the trees are new and small, they are "gone over" with tolerable regularity, but as they grow larger the novelty of the system wears off, and other work presses so hard that the necessary pinching is not, indeed cannot, be done, and nearly all the pruning is left until winter. The trees are then pruned severely, and properly so far as their shape is concerned. The branches are disposed regularly and thickly, and after the work has been done the trees have a professional business-like look. A "lot of stuff" has been taken out and preserved for flower stakes, and the work is viewed with a complacent half hopeful, yet half doubtful, feeling, that finds expression in a subdued observation that "they ought to do something." And they will do something—they will grow another fine crop of flower stakes.

GROWING FLOWER STAKES.

If the soil is good, and the roots are unchecked, young fruit trees that receive little or no summer-pinching form long and strong growths, each shoot being from 2 to 4 feet long. With the object of imparting to the trees an agreeable shape, which in itself is commendable, and also with the object of forming fruit spurs, which is again commendable, the breastwood is cut closely in, and the extremities are very much shortened. The object is good, but the mode of attaining it is erroneous. A tree thus operated upon cannot form spurs. The "art" of the pruner and cultivator renders that impossible. The system is in its nature fatal to the formation of fruit buds. They cannot form, for neither time is afforded nor material provided for the accomplishment of this desirable object. In cutting out the flower stakes the fruit-bud-forming material is removed, and time is lost in the trees attempting to provide another supply for that purpose by another season's growth. It is man warring against Nature, and both are losers. Having, as a plain man, laid down the law in a plain way, I can fancy some such question as the following being asked, with an air of doubt, if not of something more, "Do you mean to say that the long shoots ought not to be removed, and that if they remain they will form fruit spurs?" I have not framed that question so that it is easy to answer, nor in a form that I would prefer; but have put it as a natural question, even if difficult to reply to categorically.

NATURAL SPURS.

I will answer the latter part of the question first, by saying that if the long shoots are permitted to remain they will form fruit spurs, provided—and this is an all-important condition—that they are so thinly dispersed that the sun and air can act on every leaf. Natural spurs will then form the whole length of the shoots. It will take two years, or it may be three, for the fruit buds to thus form; but form on Apples, Pears, Plums, and Cherries they will, and after that there will be little trouble given by breastwood. The flower-stake-growing period will have passed, and the blossoming and (weather permitting) fruit-bearing era will have arrived. If man will just aid Nature by thinning-out superfluous shoots, and prevent others forming in their places, the branches left will become clothed with fruit spurs; but if he fights her by cutting off in winter nine-tenths of the growth formed in summer (which is often the case) he will have to wait a long time for fruit. To the former part of the question, as to whether the shoots ought to remain, the answer is, "No. It is by man's error that the thicket is produced, and the error must be repaired to give Nature a chance to do her work." The lost balance between root and branch must be restored. Such growths that impede the ingress of air to the tree and obstruct the action of light on the foliage must be removed, and further obstruction must also be arrested at its source—the roots. The roots must be partially checked, or the tree must be wholly dug up and replanted according to its size and vigour, and fruitfulness will ensue.

THE BALANCE OF ROOT AND BRANCH.

Trees which have received little or no pruning since they left the nursery grow naturally thinly, but not always symmetrically, and in

time become studded with natural spurs and laden with fruit. Where quantity of fruit is of greater moment than the shape of a tree it will be well to only prune the tree very slightly after it is five years old, but merely thin out branches that are likely to cross each other or cause overcrowding. If a symmetrical tree is of importance then it must be pruned accordingly, but the roots must have attention as well as the branches, or fruit will be sparse. As many examples prove, trees both handsome in shape and fruitful in nature may be produced by an intelligent system of manipulation, but this can only be accomplished by preventing the power of the roots overbalancing that of the branches, while at the same time root action is sufficient to sustain the tree in a healthy state. The extremes of severe restriction on the one hand and natural wildness on the other have been pointed out, and it is for the cultivator to adopt the mean that will best meet his requirements, but if fruit is the main object let him put much trust in Nature.—FRUIT GROWER

IRISH NOTES.

THE weather during the past week has been very unpleasant; the early days were fine, but towards the end we have had snowstorms at frequent intervals. The schedule for the guidance of exhibitors at the meetings of the Royal Horticultural Society of Ireland has been issued. The lists of prizes are similar to previous years, with the exception of a silver challenge cup, value ten sovereigns, which has been presented by Messrs. West & Son, College Green, Dublin, which will be given for a stand of eighteen blooms of Roses, comprising Teas and Noisettes. The dates are: The spring show, Wednesday, April 11th, at the Royal University Buildings, Earlsfort Terrace; the summer show, Thursday, July 5th, at Merrion Square; the autumn show, Tuesday, August 28th, at the same place; and the winter show, Tuesday and Wednesday, November 6th and 7th, at the Royal Dublin Society's Buildings, Ball's Bridge. Any further information can be obtained by writing to the Secretary, Mr. W. H. Hillyard, 61, Dawson Street, Dublin.

NOT A MINIATURE ROCKERY.

To those persons who admire the form and outline of rocks jutting out, or laid on a sward with some choice Alpines, shrubs, or towering trees to harmonise the whole, the natural rockery attached to the gardens of G. Orr Wilson, Esq., at Dunardagh, Blackrock, Dublin, would have attractions untold. This extensive rockery covers an area of close on two acres, and is one mass of rocks piled one upon another, wherein tortuous paths have been made, and disclose many an attractive picture when viewed from the gardens adjoining the residence. Mr. Hardy, the gardener, has only just finished those winding paths and formed several beds, but these simply await the beneficent touch of spring to transform them into life and beauty. Owing to the immense area to be covered, it will take this experienced and thoughtful gardener some time ere the rockery will be quite complete.

A USEFUL FERN WALL.

On the occasion of a recent visit to the gardens of Talbot Power, Esq., Leopardstown Park, Stillorgan, my attention was drawn to a wall on which Maidenhair Ferns in variety were growing. It formed a veritable sheet of Fern, and the advantages accruing from this mode of culture are evident, as it places at the disposal of the gardener, Mr. J. Sweeny, a practically unlimited supply of the indispensable fronds, and at the same time leaves valuable stage space free for other plants. The arrangement consists of grooved tiles running parallel from the bottom upwards, and the space available in the grooves is quite broad enough to cultivate a good sized plant. In the same house some noble specimens of that handsome stove foliage plant *Anthurium crystallinum* were to be seen. The large dull green leaves and the prominent silver veins look exceedingly well; the specimens are placed at intervals, between which various plants are fittingly disposed.—A. O'NEILL.

CRINUM AUGUSTUM.—The genus *Crinum* is productive of a very large number of handsome flowering species, many of which are highly thought of by the horticulturist for the decoration of stove or greenhouse. That under notice is one of the showiest of the genus, and deserves universal attention. It is a native of Mauritius and the Seychelle Islands, and requires a stove temperature. By reason of its foliage alone it is a striking plant, the leaves often being from 3½ to 4 feet long and 5 inches wide, occasionally exceeding those dimensions. The flowers are produced in large spreading umbels, on scapes 3 feet high, from fifteen to twenty blossoms being often contained in each head. Individually they are large and showy. The corolla tube is from 5 to 6 inches long. The perianth segments are long and spreading, making the open flowers often 7 inches across. With the exception of the inner side of the segments and the anthers the whole flower and upper part of the scape is of a deep red colour. The anthers are bright yellow, while the other excepted portion has a white ground deeply stained with red. The plant is of easy cultivation, provided it has good loamy well-drained soil, with abundance of heat and moisture during its growing season, and a three-months rest in winter.—W. D.

Recent Weather in London.—Towards the end of last week we had a change in the weather, which brought on Friday night and Saturday morning a very heavy fall of snow. With a cessation of the fall a thaw set in, and continued gradually until Tuesday night. It was very slow, and accompanied by bitterly cold winds on almost every day. The sun shone for a brief period on Tuesday. There was a sharp frost on Wednesday morning, which continued to the moment of going to press.

Weather in the North.—February brought a change to more seasonable weather. There has been a succession of clear sunny days, with occasionally a slight overclouding and a light snow shower. Frost has been continuous since the 1st, 11° being registered on the 2nd and 13° on Monday, which day was bright and clear throughout, with every appearance of continued frost.—B. D., S. Perthshire.

Royal Horticultural Society.—The next meeting of the Royal Horticultural Society will take place in the Drill Hall, James Street, Westminster, on Tuesday, February 13th. The various Committees will assemble at noon as usual, and at three o'clock the annual general meeting of the Society will be held at the Society's offices, 117, Victoria Street, Westminster, S.W. The Council of the R.H.S. at its last meeting unanimously requested the President, Sir Trevor Lawrence, Bart., to allow himself to be appointed to the vacant Victoria Medal of Honour.

Cross-Fertilisation of Cereals.—On Monday afternoon a meeting of the members of the Farmers' Club was held at the Club, Salisbury Hotel, E.C., when Mr. Gaiton, the well-known authority on the cross-fertilisation of farm plants, gave an interesting address on scientific plant breeding. Mr. Gaiton said that it had been proved conclusively that there was no cross-fertilisation in Nature, but by artificial methods English farmers would be able to grow better crops. Experiments in breeding had been carried on on an extensive scale at Newton-le-Willows, and was largely assisted by the late Earl Winchelsea. The result of their researches had been offered to the Government in order to assist agriculture, but the only reply that had been received was to the effect that there was no department capable of developing the experiment, nor any funds to assist the movement.

Too Early Seed Sowing.—The time is rapidly approaching when the attention of growers will be turned to the sowing of both flower and vegetable seeds for transplanting later in the open. Many who are anxious to begin will do well to carefully consider the concluding paragraph of the article on page 44, referring to these operations. It may not be necessary to tell practical gardeners when to sow their flower seeds, but even they sometimes err on the side of too early sowing, and it is a too common practice to sow the seeds of Asters, Stocks, and other half-hardy annuals in strong heat in February, instead of waiting a few weeks longer, when the plants can go from the seedling to the flower stage without the check that is inevitable when they have to be kept in a confined root-bound condition, brought about in most cases by the grower's anxiety to get a little ahead of the season.—G.

Indian Gardening.—On more than one occasion it has been our pleasure to congratulate the Editor of this Indian periodical, and we cannot let pass a further opportunity. This arose with the new year, when the conductors added another distinct section of the paper, which will be devoted to Tea, Coffee, Indigo, and economic products generally. The departure has been to a large degree forced upon the Editor by correspondents seeking information, which could not adequately be given without encroaching on the space devoted to horticulture. Several pages have been added, and they are full of interesting matter. So far as the original section is concerned we again notice improvement in the paper, which now takes half tone blocks, and brings the details out admirably. We can only add, that if the new section is as sound and as interesting as the old, it must prove an unqualified success.

Death of Mr. Smith, Sen.—Mr. E. D. Smith writes from Carshalton:—"I have just lost my father, who came to live at Gravesend shortly before we left there, and managed a small place at Rosherville. He had an attack of paralysis, which necessitated his being in the hospital for three months. He died on January 26th, and was buried at Gravesend on Thursday last. He was seventy-three years of age." [We sympathise with our coadjutor in his great trouble.]

Native Guano.—The Secretary of the Native Guano Company, Ltd., 29, New Bridge Street, Blackfriars, has favoured us with a 56-page pamphlet of testimonials. These number some hundreds, and have come from all parts of England and Wales, and must of necessity represent many kinds of soils and crops. All, however, testify to the excellence of this plant food, which has attained to very great popularity since it has been before the public.

Southern Counties' Carnation Society.—The second annual report of this Society shows a condition of affairs that must be gratifying to all concerned. Indeed, in the Committee's official report we find the following sentence, which conveys an excellent idea of how matters stand. "Without invidious comparison, your Committee cannot but feel great satisfaction, that, in the second year of its existence only, it is second to none in the provinces, and they accept this as a mark of approval of the lines upon which the Society is carried out." The schedule of the show for this year is also provided, and comprises many classes with capital prizes. There are in addition to those items some articles on Carnations by experts. The Honorary Secretary is Mr. W. Garton, jun., York Buildings, Southampton.

Isle of Wight.—On Thursday last a public meeting was held in the Newport Guildhall with the object of forming a local Chrysanthemum Society. Mr. W. Morris, an old exhibitor, presided over a small attendance. After an animated discussion it was resolved, on the motion of Mr. W. E. Wickens, that a Newport Chrysanthemum Society be established, and that an exhibition be held in November. A Committee was afterwards elected, with F. T. Mew, Esq., J.P., C.C., President, Dr. M. T. Coombes Treasurer, and Mr. C. H. Cave Secretary. On Saturday last the Isle of Wight Horticultural Improvement Association held its adjourned annual meeting at Warburton's Hotel, Newport. Dr. J. Groves presided over a good attendance. The members decided to elect local Committees at Cowes, Ryde, Shanklin, Ventnor, Freshwater, and Newport, with seven members each. It was decided to amalgamate with the Ryde Horticultural Society in the holding of an exhibition of spring flowers at Ryde Town Hall on April 19th. It was resolved a fruit and honey show be held at Newport in October next. It was also decided to award the Association certificates to meritorious exhibits staged at any of the Island shows during the year 1900. The programme of lectures for the current year was left in the hands of the Secretary, also the places of meeting. A sub-committee was appointed to make arrangements for printing in book form the lectures given at the meetings, with other useful information. The meeting was brought to a close by the election of seven new members.—S. H.

Chester Paxton Society.—The annual social gathering of this Society was held on Saturday at the Grosvenor Museum, when about 150 members met under the presidency of Mr. Robert Wakefield. Tea was served in the Art Gallery, after which an entertainment was given in the lecture theatre. The chief item of interest in this was an illustrated lecture on the Transvaal war, by Mr. J. D. Siddall. Mr. Siddall's lucid descriptions of the chief places of interest in South Africa, aided by an excellent set of lantern slides, enabled the audience to follow intelligently the principal events which have happened in the Transvaal during the past year. In addition to this a musical programme was well carried out by Mrs. Simon, Miss and the Masters Weighall, Mrs. and the Masters Miln, Mr. E. Ward, and Mr. T. Brook Edwards as accompanist. All of these acquitted themselves most creditably, as was very evident by the applause from the audience, and the rendering of "Soldiers of the Queen" and "Absent Minded Beggar" resulted in a good collection for the war fund. At the conclusion of this programme Mr. N. F. Barnes proposed, and Mr. John Wynne seconded, a hearty vote of thanks to all who had contributed to the evening's enjoyment. Mr. Siddall in responding said that it had given himself and the others great pleasure to entertain the members of the Paxton Society, and hoped that the Society would have many other similar gatherings in the Museum. On the initiative of Mr. Miln, the President was also thanked for his services, and the singing of the National Anthem brought a very enjoyable gathering to a close.

The Value of Birds.—A French naturalist asserts that if the world should become birdless man would not inhabit it after nine years' time, in spite of all the sprays and poisons that could be manufactured for the destruction of insects. The bugs and slugs would simply eat up all the orchards and crops in that time.

The Imperial Yeomanry.—Mr. Harcourt Webb and Mr. Frank Webb, sons of Colonel William G. Webb of Wordsley, Stourbridge, who, after holding commissions in the 1st South Staffordshire Volunteer Battalion, recently joined the Imperial Yeomanry, embarked for South Africa on Saturday. Their many friends in the Stourbridge district abound in good wishes for them, and in the hope for their safe and early return.

The Oldest Tree in the World.—The oldest tree in the world is reported to be an Oak, on the island of Cos, in Asia Minor, which, according to a painstaking German investigator, has attained the very respectable age of 2900 years. The authority has arrived at this conclusion from a careful examination on the ground. Tradition has it that the philosopher Hippocrates, who was born on the island, often assembled his pupils under the welcome shade of this very tree's branches. Now Hippocrates lived five centuries before the Christian era, and if this is the same old tree, it has indeed established a fine record for longevity. The trunk of this ancient Oak has a diameter of over 27 feet.

The Late Duke of Teck.—At a Committee meeting of the Richmond Horticultural Society, specially convened for the purpose, Mr. Thomas Skewes-Cox, M.P., in the chair, the following resolution was unanimously adopted: "That the Richmond Horticultural Society hereby places on record its deep regret at the loss which has befallen horticulture by the death of his Highness the Duke of Teck, G.C.B., a prince who for no less than twenty-six years past had been the President and valued friend and supporter of this Society, and begs to tender sincere and respectful sympathy to their Royal Highnesses the Duke and Duchess of York and the other members of the late President's family in their heavy bereavement."

Damage by the Snowstorm.—The heavy snowstorm we experienced last Friday night must surely have wrought great damage to shrubs and trees of various descriptions throughout the southern counties. In the grounds here numerous branches and the tops of several Rhododendrons, Arbutus, Cedars, and Pines were broken off during the night by the wet heavy masses of snow, which on the level lay to a depth of quite 6 inches. Tall Junipers and Cryptomerias were bent nearly double by their unaccustomed burden, whilst clumps of Gorse and Broom were flat on the ground. The snow is disappearing very slowly, which will benefit the ground more than a rapid thaw would do by sinking gradually into the soil, which in many places, more especially in clumps of shrubs, has not recovered from the terrible drought of the past two summers.—T. H. BOLTON, *Coombe End*.

The Snow.—There is a pretty notion prevalent that snowfalls are providential dispensations purposely intended to protect plants out in the open from hard frosts and biting winds. No doubt such results follow in the Arctic regions and in the countries of almost perpetual snow. But in Great Britain our snows are usually of a very prosaic order, and generally become an intolerable nuisance. Hills and dales covered with the white frozen vapour may be temporarily pretty and even picturesque, but the eye soon tires of the glittering whiteness of the scene, let it be ever so unwonted. But snowfalls in a town are horrors. What misery they cause to everyone. Not even poets of the order of an Austin or a Kipling could find in a town under snow anything to arouse the muse of rhyme, if not of song. We have just had for the South a heavy snowfall, varying in depth from 4 to 6 inches. It was a soft snow, and followed by great mildness, so that the frozen vapour began to disappear rapidly. But the plant protection theory had not a peg on which to hang an axiom or a sonnet. There was neither frost nor biting wind following. The plants might well have complained of the scare thus created. Why thus envelope them in snow? Why thus profess to furnish them shelter and protection when there was no wolf-like frost prowling about, no fierce beast howling for its prey? To gardeners unnecessary snow brings great inconvenience, but during such a winter as the present, for instance, its primary compensation is found in the quantity of moisture it imparts to the soil, and in a gradual way. Still the quantity of moisture thus furnished is relatively small, for 6 ins. of snow probably does not furnish when it is dissolved more than one-third of an inch of water.—A. D.

Pitcairnia corallina.—Bromeliads as a rule are a neglected race of plants. Some without doubt do not deserve a place in gardens, where room is limited, but there are others which are very showy, as evidenced by the display of species and hybrids exhibited at Chiswick in July last, on the occasion of the Hybridisation Conference. To the showy section the one under notice belongs, and by many people is said to be the finest of the whole set for decorative purposes. The plant is of ornamental character throughout. The leaves are from 4 to 5 feet long and 4 inches wide in the centre, narrowing to a long petiole at the base, and to a point at the apex. They are silvery in colour, and armed along the margins with a few thick spines. The flowers are about 1½ inch long, of an exceptionally bright coral red, and produced forty or fifty together on drooping racemes 18 inches long, the same colour as the flowers. A fine specimen, bearing several inflorescences, may be seen in flower in the Victoria Regia house at Kew, where at the present time it is by far the most conspicuous object.—K.

Sussex Weather.—The total rainfall at Abbot's Leigh, Haywards Heath, for the past month was 3.57 inches, being 1.44 inch above the average. The heaviest fall was 0.73 inch on the 6th. Rain fell on twenty-one days. The maximum temperature was 51° on the 2nd, 23rd, and 24th; the minimum 24° on the 14th. Mean maximum 44.24°, mean minimum 34.05°; mean temperature 39.14°, which is 2.08° below the average. A cold wet month, with frequent slight frosts. There was a considerable fall of very wet snow on the 27th and 28th.—R. I.

January Weather at Belvoir Castle.—The prevailing direction of the wind was S. on eighteen days. The total rainfall was 3.16 inches, which fell on twenty-five days, and is 1.38 inch above the average for the month. The greatest daily fall was 0.90 inch on the 6th. Barometer (corrected and reduced): Highest reading 30.469 inches on the 11th at 9 A.M.; lowest 29.330 inches on the 28th at 9 A.M. Thermometers: Highest in the shade 52° on the 23rd; lowest 25° on the 21st. Mean of daily maxima 43.19°; mean of daily minima 32.87°. Mean temperature of the month 38.03°; lowest on the grass 22° on the 1st and 2nd; highest in the sun 80° on the 27th. Mean temperature of the earth at 3 feet 39.03°. Total sunshine, twenty-four hours fifty minutes. There were sixteen sunless days.—W. H. DIVERS.

The Weather in Bedfordshire.—The 2nd inst. was heavily overcast all day, with a keen north-easterly wind; at night the wind abated and snow began to fall, continuing all night, and in the morning the depth was 7 inches, the heaviest fall at one time for some years. The night generally was still, and the flakes of snow were very fleecy, so that wherever they fell on trees, shrubs, and hedges it was nearly the same thickness as that on the ground, and consequently the weaker growing shrubs were prostrated, and the more brittle kinds, such as Aucubas, were in several cases broken. I learn that in the neighbourhood several fine Cedars of Lebanon have suffered. Fortunately the following day was calm, or much more damage would have resulted. The landscape is still covered with snow, although a slight thaw has continued since Saturday, but the temperature is very low, and garden work practically at a standstill.—G. R. ALLIS, *Old Warden, Biggleswade*.

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet.

The weather during the week has been remarkable for cold north-easterly winds. Sleet and rain fell on Friday, followed in the evening by snow, to the depth of 3½ inches.

DECADENCE IN WALL TREES.

A WRITER to the general Press has been more than once heard to say that nothing was so depressing as to be taken no notice of; to be praised, he said, was gratifying, as it appealed to one's vanity; to be adversely criticised was useful, as it afforded a theme for another discourse; even to be abused a little was helpful, as it acted as a stimulant; but to be ignored was positively enervating. If I were to share those views I ought to be doubly thankful to Mr. Oldhead, who, on page 93, seems both to chide me and praise me for the communication on page 52, with which he curiously deals.

First he would seem to imply that wall trees are all right if you will but let them alone, or at least those that are in the hands of "gardeners," and not a slur must be cast on their vocation. On their "vocation" certainly not. Then my friendly critic affects not to understand what a "modern go-ahead gardener" is. Has he not read the *Journal of Horticulture* wherein the "modern" has declared himself as having no time to train the branches of fruit trees "straight as a gun barrel," as Mr. Temple advised on page 77? But all he tries to do is to rush them up the wall as fast as he can to get fruit. The shape of the trees and the regular disposition of the branches are nothing to him; he simply wants fruit, and wants it quickly. He obtains it quickly; but he does another thing, though that does not count for his purpose—he spoils the trees quickly, too.

Perhaps Mr. Oldhead is a comparatively new reader, and has not seen such narratives; but if he is not a very young gardener, and has had reasonable facilities for getting about, he may have come in contact with such men and such rapidly "trained" trees, which, for the creditable furnishing of walls in private gardens, are exactly what they ought not to be. The modern fashion is to adopt the market growers' plan with trees and Vines: run them up quickly, crop them early and heavily, exhaust them prematurely, then root them out with as little compunction as if they were Cabbage stumps, and plant more.

I should like to take another point in my friend's letter. I refer to him as "friend" for his being so good as to enable me to note and subject the point to the gentlest of analysis. After telling us in these columns of the "epidemic" of neglected wall trees, and even approving of my remarks as embodying an elementary lesson and deserved castigation to recalcitrants, he complacently tells us that the *Journal of Horticulture* is not the right place for me to point out such shortcomings. "As well," he intimates, "address my remarks to Queen Victoria." Let me, in reply, say, Not quite; for has he not read, as most old-headed gardeners have, over and over again, that the wall trees of the Queen are proverbial for the skill displayed in their training as well as for productiveness? I have read many such allusions to them, and have often thought I should like to see the handiwork of the Royal pruners and trainers in covering garden walls attractively and profitably at the same time.

This combination is to be found in other gardens, and when seen is always admired. But the examples are few in comparison with those of the earlier years of the century; then they were the rule, but now, unfortunately, the exception. Practically all the old masters in training who are still living must know that it is so, admit it, and regret it; indeed there is not wanting a glimmer between the lines of Mr. Oldhead's letter that he is one of them; at least he assumes to know the cause of the evil.

As to the suggestion that those gardeners who have not acquired the art of training fruit trees as objects of beauty with utility, not being readers of this Journal, I am able to assure my brief, though lively, critic that in the two instances of spoiled trees specified in my notes on page 52, both gardeners in whose charge they are take the paper weekly, and as one of them had received a private lesson on the method of treating the trees for effecting some possible improvement, he was not surprised by the reference; nor does he resent it. He is in many respects an excellent man, a splendid plantsman, and good Grape and vegetable grower, but in his training in three gardens had never had a lesson in the proper management of wall trees from their youth upwards, and had never had the subject impressed on his mind as one of importance. He knows it is now. In the other instance the gardener found the trees in the deplorable state described, and is doing his best with them, but it is impossible for him or any man to make them what they ought to be. It may perhaps be stated as a fact, and not without significance, that because of the unsatisfactory condition of the wall and other trees, the nurseryman who supplied them was wrongly blamed, and when this was made clear the real spoiler of the trees had to "go." He really paid little or no heed to them, his thoughts and sympathies being concentrated in other directions.

On the question of the growths of fruit trees extending 3 or 4 feet above the top of a wall, which trees Mr. Oldhead imagines cannot be in the hands of a "gardener," I have no objection to giving him an example of my own ignorance. Half a dozen years ago I was invited by a gentleman to examine his garden and fruit trees. Fifty or more years previously the Pears on a long but not very lofty wall had been beautifully trained, but the last dozen years or so they had been grossly neglected. The mansion had been for a time unoccupied, and the garden let to a local greengrocer, who was to keep the trees in order. There was practically no growth over the face of the wall, beyond dwindling attenuated spurs, absolutely incapable of bearing fruit. The trees grew from the top only above the wall every summer, and the

shoots were levelled down every winter. The trees were like top-heavy old espaliers, occasionally seen in ancient gardens, and which, treated in the same way, bear little or no fruit.

The new tenant, who had taken the residence for fourteen years, wished to know how the old trees could be made to bear. He was advised to root them out and plant cordons, which would pay him over and over again during his lease. He said "no," most emphatically; he was not going to plant for whoever might come after him. He was then told he could get no fruit from the branches of the trees against the wall, but might have Pears, if he would let the branches grow above it. To that he had no objection at all, but rather liked the idea, as the fringe along the top would form a screen from neighbouring windows.

The advice thereupon given was this. Let some of the growths above the wall remain unshortened, these to be about a foot apart. Cut out all others between them, and permit no others to grow in their places, but rub all spring shoots that threaten to do so clean out by their sockets, then the young unshortened branches will produce blossom buds in two years, and weather permitting bear fruit. The gardener the gentleman brought with him agreed. There is now a hedge along the top of the wall, and ten times more fruit has been obtained from it than from all other parts of the trees, or than they had borne for five years previously.

This is mentioned for two reasons. 1, To show that I am not a faddist and would be content with straight equally disposed branches and no fruit. 2, That there are gardeners, or "so-called," who really would allow such extensions when fruit could not be otherwise had from such trees. All the same, it would have been better to plant cordons, and thus render the wall ornamental and useful, as all the boundary walls of gardens ought to be—covered from base to summit with straightly trained fruitful branches, whatever form the trees may be, cordons, horizontals, fans, or palmette verriers.

Mr. A. N. Oldhead will note the singular coincidence that my initials are the same as his, but I cannot help that; it may be fortunate in that it may perhaps dispose him to treat this my rejoinder tenderly.—A. N. O.

APPLES AND FROZEN WATER PIPES
SPLITTING.

WITH regard to the differing views held by your correspondents, as to when water contracts and when it expands, is it not possible that both factions may be partly right? I believe it is a well understood chemical law that water reaches its maximum density at 4° Cent., or 39.2° Fahr.; and being an exception to all other liquids, expands both above and below that temperature, so that the water pipes of "A. D.," and the thin-skinned Apples of "H. Richards" might both have been burst by the same means—namely, the expansion of water.

I scarcely think that Mr. Richards has ever seen a frozen pipe burst by applying heat to it, as the ice would first have to be thawed, and then the water heated to 39.2° before it began to expand again, and it would require considerable heating to cause it to occupy a space greater than that taken up by the ice. He probably did not notice that the pipe was burst till the water began to leak out.

I rather fancy that Mr. Richards would have to plug up his pipe at both ends to prevent any escape, and then boil the water in it to get it to burst. However, to some of us, who may have neither time nor inclination to amuse ourselves with water pipes, marmalade jars and tobacco tins, the word of those scientists who have made a study of the subject is sufficient.—A. DAY, *Herts.*

ERE "rushing in" with another moral to adorn this lively tale, one would like to propound another question, the answer to which should throw some light upon the matter—viz., What killed the man who fell from the church steeple? was it the fall or the sudden stop? I think Mr. Richards will admit that, as a rule, the effect of frost is not easily seen until the thaw sets in; but that the effects are there, whether it be ruptured vegetable tissue or fractured pipes, seems to be clear. That the application of heat, whether of solar rays on the one hand or of fire heat on the other, accentuates the evil is obvious.

Heat expands some objects, if there is room for expansion, but if frost has not room for expansion it will split a mountain to vent its mighty force. With heat this is not the case, unless there is room to generate steam, then it would disembowel the earth itself. The hardest nuts to crack are often minus a kernel, but if Mr. Richards will tackle this one he will doubtless be rewarded for his pains, although it may somewhat painfully shatter his statement, "Engineers always leave vent for expansion." Thirty years ago there was a system of hot-water heating on the Continent which comprised a copper boiler and a single 6-inch copper pipe carried the length of the plant house. These—boiler and pipe—were filled, absolutely filled, when fixed (no room for expansion, no room for steam, no room for anything), and then hermetically sealed, and in the normal course of things not touched afterwards. By this system, if memory serves aright, it is possible to raise the heat of water to about 600° Cent. This system was described (and illustrated to the best of recollection) in the "Revue de l'Horticulture Belge," a monthly magazine which then (thirty years since) filled up a niche in the bothy leisure of—A. N. OLDHEAD.

CINERARIA CULTURE.

CINERARIAS are amongst the most brilliant of greenhouse plants, and without much difficulty they may be had in bloom late in autumn and onwards through the winter, though the most important display of fine plants and large heads of bloom is usually found in February or March. The chief enemy to guard against in Cineraria culture is the

FIG. 28.—CINERARIAS AT PERRY HILL.

aphis or green fly, and plants in or approaching bloom now require the coolest of treatment consistent with keeping out frost from the structure in which they are growing. When plants become attacked with the pests they ought to be frequently fumigated with tobacco paper or vaporised with nicotine, the latter being the better method. Special attention should be given to freeing the plants previous to flowering, as they suffer considerably in appearance if the aphides are allowed to increase upon them. They not only abstract the juices from the foliage, and cripple growth, but they leave a deposit which mars the appearance of both leaves and flowers.

This enemy is largely encouraged to attack the plants when they stand on open shelves in a dry heated structure. To prevent this the stage should be covered with some moisture-holding material, and the heads of the plants situated not far from the glass. A temperature of 40° to 50° suits Cinerarias best, and in it they will progress healthily and steadily. A little shade is beneficial to the plants when in full flower during March or April in strong sunshine. At this period, too, the pots are full of roots, therefore watering must be regular, and be given in sufficient quantity to pass through the whole ball of soil and roots whenever the least dryness is apparent on the surface. Cinerarias soon feel the stint of water, and the foliage droops and is distressed in consequence. Liquid manure may be given to healthy plants well furnished with roots, but not before they show flower spikes, and it ought never to be applied in a strong state. The applications must cease when the blooms begin to open fully, sustaining the growth afterwards with clear water.

Cinerarias are best raised from seeds, employing a good reliable strain. The single varieties are the more useful. For an autumn display sow seeds in March and April. To furnish plants for the spring display later sowings in May or June are soon enough. Prepare shallow seed pans by effectively draining with a well placed layer of crocks, covering them with moss or clean fibre, so that soil cannot be washed down among them. Next introduce the compost, which should be composed of sweet fibrous loam and leaf soil made porous with sand. Thoroughly mix the whole together into a moist, but not a wet condition. Fill the pan to the brim, level, shake down, and press smoothly. Give a gentle watering with a fine rosed can, and after draining sow the seeds thinly on the surface. A mere dusting of sand or soil will suffice to cover the seed.

No further watering should be needed until germination has taken place, and it will not be necessary if the evaporation of moisture from

the soil is prevented by placing the pan in a moist position and covering with a pane of glass and paper. The latter must not remain after the seedlings have pushed through the covering, and the glass may be gradually dispensed with, elevating the pan close to the light in an airy, cool greenhouse. Shade from strong sunshine, and when the soil shows that water is needed immerse the pan to the rim in tepid water, not to flood the surface, but so that it can percolate through the soil from below. Immediately it shows on the surface withdraw the pan from the water.

If the seedlings are not crowded they may be allowed to progress to a considerable size before pricking them out singly to strengthen, but they must not remain in the seed pan to injure one another. Similar compost to that used for sowing the seeds may be employed for the transplanting. The largest plants are not always the best, and it may safely be asserted that those seedlings which take the lead in growth are not the plants which are capable of producing the best flowers, therefore do not discard the smaller. Pricking out the seedlings is essential, as it affords them room to grow, and causes fibrous roots to be developed, which are of great assistance when placing the plants in their first pots. From the time of pricking out the seedlings, which may be done in pans or boxes, cold frame treatment will be the most appropriate. If the frame is not in a shady position, shade the seedlings from strong sunshine. Sprinkling the plants daily will insure sufficient moisture until they become better established, when more water may be given.

The next move may be to 4-inch pots, using a compost of two parts loam, one leaf soil, one decomposed manure, and plenty of sand. The plants grow better if potted rather lightly. Place them in a cold frame in a north aspect, where shading will not be required. The pots should stand on a moist base of coal ashes, which also excludes worms from the soil. Maintain the frame close for a time, but after growth has recommenced admit air more freely. Sprinkle the plants daily in dry hot weather, and afford water to the roots as required. Place the plants in larger pots when these have become filled with roots, still continuing frame treatment with abundance of air. In July and August the lights may be removed, especially at night, so that they may receive the benefit of any dew which may fall, but protect the plants from very heavy rains.

Cineraria stellata, the Star Cineraria, hybrids of *C. cruenta*, the result of crossing the old *C. cruenta* with the greenhouse variety, produces large heads of flowers on long stalks, the individual blooms, however, being smaller than the ordinary single Cinerarias. It is free flowering, and admirable for decoration and cutting. The method of cultivation is similar to that accorded the ordinary form. For certain

FIG. 29.—GROUP OF CINERARIAS.

positions in large conservatories it is splendidly suited, as also is it for providing an abundance of cut flowers.—E. D. S.

[Many of the catalogues issued periodically by the nurserymen and seedsmen of this country are fast becoming true works of art, and amongst the foremost this season is that of Messrs. Carter & Co.,

High Holborn. The firm has, on the present occasion, embodied in its "Vade Mecum" a history of the house, which was established in 1804. Photographic reproductions of the covers of ancient and modern catalogues are given, as also are illustrations of various portions of the extensive seed warehouses, with views of the nurseries at Perry Hill, Mortlake, and the seed farms in Essex. The Perry Hill nursery is devoted to florists' flowers, and Cinerarias form a prominent feature in

beautiful and make a more attractive display than the double forms will be generally acknowledged, but, at the same time, the latter ought not to be omitted entirely. In establishments requiring large numbers of flowering plants it is desirable to obtain a sufficient stock by the aid of several different kinds of flowers, and it is here that the value of the double Cineraria is most highly appreciated. The flowers are distinct in form, and are now to be procured in various colours, and

FIG. 30.—AN ORCHID SHOW HOUSE.

their season. By the courtesy of Messrs. Carter & Co. we are enabled to place before our readers one of the houses of Cinerarias when in full bloom (fig. 28), and a group (fig. 29) of the same plants arranged at one of the exhibitions of the Royal Botanic Society.

As our contributor confines his remarks on propagation exclusively to the raising of stocks from seeds, it may naturally be inferred that he is advocating the culture of single Cinerarias. That these are more

these, like those of many other plants, have improved very materially of late years. Not only are double Cinerarias superior in colour, but the habit of the plants has become more compact, and this without any indication of stubbiness. These, like the single varieties, can be readily raised from seeds, but it is advisable where a particular colour is wanted to propagate from cuttings in the manner that was adopted for all Cinerarias in the days gone by.]

"THE ROSARIAN'S YEAR BOOK."

VERY many years have come and gone since "The Rosarian's Year Book" first saw the light, but it, nevertheless, under the skilled and loving guidance of the Rev. H. Honeywood D'Ombraïn, maintains its popularity and its practical utility. Each year brings its new edition and each issue contains something different from its predecessors, and consequently the interest continues unabated. It is a labour of love for the great florist, as is everything in connection with the flower he knows so well, and at whose shrine he has worshipped for such an exceptionally prolonged series of years.

The "Year Book for 1900" has for a frontispiece a speaking portrait of that excellent amateur rosarian, Mr. Henry Vessey Machin, of Gateford Hill, whose photograph has appeared in the *Journal of Horticulture* on more than one occasion in connection with "big wins." The sketch of Mr. Machin's life is from the graceful pen of Mr. Chas. J. Grahame, who speaks highly of the enthusiasm of this the largest of amateur Rose growers. The Rev. J. H. Pemberton, whose renown as an exhibitor is second to none, has some "Recollections of Some New Roses of 1899," while Mr. George Paul, V.M.H., deals in the style of a master with "Garden Roses: Planting and Pruning." The Editor takes as his text "The Rose and the National Rose Society in 1899," and gives a most interesting article. "Amateur Rose Culture," by Mr. R. E. West, is excellent and worthy of this successful grower. He is always practical and yet continuously readable, and his advice can be explicitly relied upon, especially that about maggots, which says:—

Maggots fat, maggots lean,
Maggots large, maggots green,
Maggots long, maggots short;
Catch 'em soon, or Roses nought.

Mr. Cecil E. Cant dilates upon "Standard Roses," with which he is fully qualified to deal. As in his opening sentence he objects to some of the references to this form of Rose culture that appear in the gardening Press we have reproduced his contribution in the hope that it may prove serviceable to our readers. As is customary, the conclusion of the book is left to Mr. E. Mawley, and his topic is "The Weather of the Past Rose Year," and this, though last, is not the least valuable of the contributions.

STANDARD ROSES.

One frequently reads in the gardening papers articles on standard Roses, but the summary of them generally amounts to how not to grow them, or ends in advice not to give them a trial, but the real origin of their want of success in some gardens has more to do with the selection of unsuitable varieties than anything else. How often one comes upon a stem with no head to speak of, and yet is supposed to do duty for a standard. On looking at the label one finds Horace Vernet, or Boildieu in a lingering death. Such varieties and notorious bad growers should never be grown, and are entirely the cause of the outcry against standards; but if a careful selection of suitable varieties is made, standards are very useful in various ways—viz., to form a background of two or three rows of dwarfs, as a centre to round or oval beds, also for planting out in conservatories; then again, they are best in small enclosed gardens, as the height of stem brings the head free of other growths and to a brighter atmosphere; as an aid to success at the exhibitions the standard Teas and Hybrid Teas are indispensable, and the standard as a weeping plant can be used with great effect.

Now, to deal with the last first. Standards on stems 5 to 7 feet high, to be planted singly in various parts of the garden, or to form a centre in a large bed, make very handsome and attractive objects. They must be firmly staked, and the long, trailing shoots should be arched over and tied to the stem, umbrella fashion, to grow as weepers. After one season the shoots will retain their positions, send out lots of laterals, and thus form a handsome tree, blooming freely throughout the summer. The best sorts for treating in this way are Aimee Vibert, white; Celine Forestier, yellow; Claire Jacquier, yellow; Crimson Rambler; Felicite Perpetue, white; Fulgens, crimson; Longworth Rambler, red; Madame Alfred Carriere, cream; Paul's Carmine Pillar; Paul's Single White; Reine Olga de Wurtemberg, red; Rêve d'Or, yellow.

One often hears at the great Rose Shows, "How is it so-and-so gets his Teas so large and full, such colour and so clean?" The answer nearly always is, "They are grown on standards and half-standards, thus keeping the blooms off the ground, away from many enemies, and clear of the splashes from heavy rains." Then, again, these

exhibitors of extra fine flowers will tell you more good! blooms result from one standard Tea than from four times the number of dwarfs, and they are quite right, as my experience goes. The standard Tea has suffered in the past from very sharp frosts, but a hardier race seems to be with us now, and to winter safely, with slight protection during very severe weather.

The following varieties of Teas and Hybrid Teas make excellent standards for either show or garden decoration:—

Hybrid Teas.—Antoine Rivoire, Caroline Testout, Clara Watson, Kaiserin Augusta Victoria, La France, Madame Cadeau Ramey, Mrs. W. J. Grant, Viscountess Folkestone.

Teas.—Anna Olivier, Bridesmaid, Catherine Mermet, Cleopatra, Comtesse de Nadaillac, Ernest Metz, Ethel Brownlow, Hon. Edith Gifford, Innocente Pirola, Jean Ducher, Madame Cusin, Madame de Watteville, Madame Hoste, Madame Lambard, Maman Cochet, Marie Van Houtte, Medea, Muriel Grahame, Rubens, Souvenir d'Elise Vardon, Souvenir de S. A. Prince, Souvenir d'un Ami, The Bride, White Maman Cochet.

The standard Hybrid Perpetuals and one or two of the climbing varieties are not recommended as aids to prizes, but are very useful in beds and borders, and as there must be some good rich colours amongst the pale Teas to set them off, the following sorts can safely be relied on to give satisfactory results:—Alfred Colomb, Auguste Rigotard, Boule de Neige, Baroness Rothschild, Bouquet d'Or, Clio, Dr. Andry, Duke of Edinburgh, Dupuy Jamain, Gloire de Dijon, Général Jacqueminot, Homer, John Hopper, Jules Margottin, Madame Berard, Madame Clemence Joigneaux, Madame Gabriel Luizet, Madame Victor Verdier, Magna Charta, Margaret Dickson, Merveille de Lyon, Mrs. John Laing, Madame Isaac Pereire, Monsieur Boncenne, Mrs. Paul, Paul Neron, Thomas Mills, Tom Wood, Ulrich Brunner, William Allan Richardson.

For conservatories, either for planting out or planting in beds outside and bringing the heads under glass as with Vines, the standard is indispensable. Many climbers and other varieties grown in conservatories must necessarily be planted under staging; the stem gets over the difficulty by bringing the head above the stage and obtaining the light necessary for its success. Such sorts as Maréchal Niel and Climbing Niphetos do splendidly in this way, last for many years, and give good crops of fine flowers, where dwarfs in similar positions would lack the light and never be a success.

There is no desire in these remarks to praise the standard beyond its merits, but simply an endeavour to prove there is worth in it, and that it is a good companion for the dwarf in many ways, and given suitable positions it will greatly aid in garden decoration.—C. E. CANT (in "The Rosarian's Year Book").

PRUNING MARÉCHAL NIEL.

"H. S." (page 92), accustomed with success to prune his own specimens of this Rose under glass by cutting away almost all the wood of the year immediately after flowering, is yet doubtful whether it is the better method, because of a comparison between this and a lighter style of pruning that he has seen in another man's house.

I do not think he gives us quite enough data to judge of the matter properly. For pruning such plants after the first year's growth and subsequent flowering, everything depends upon how much space each plant is intended ultimately to cover, and what progress it has made towards it. The house in question would probably be of the ordinary height; but how many rods—that is, what width of roof—was each plant expected to supply and cover? It seems plain, from the statement of the case, that none of them covered anything like the allotted space (as might be expected) the first year, for the best of them, slightly pruned, only got to the top of the house the second year.

These Roses had only been planted one year, and not having made luxuriant growth had probably not very strong root power. To cut away almost all the growth, and with it all the foliage in the midst of the growing season, is a severe check to any plant, and I advise that even with the strongest and best established it be done as gradually as possible as the blooms are gathered; and as these plants were not very strong, and had not each (apparently) covered more than half the space intended, it was clearly better that year to give them the benefit of their leaves, and avoid any check till the allotted space was covered.

It is, after all, only a question of room below and above. When once the available space for the plant is covered, what are you to do with the strong young rods formed in summer and autumn? and if such are not formed you will get no fine blooms. If, on the other hand, there is more available space to be covered, and a corresponding amount of room and food for the roots below, then go in for "extension," and do not prune so hard till the space is covered.

I agree that short standards are generally best for this work. My own plant, which gives me from 300 to 400 blooms every spring, was planted fourteen years ago, and has not said anything about dying yet.—W. R. RAILLEM.

NOTES ON ACACIAS.

THESE are among the most easily cultivated of greenhouse plants. Some have a tendency to make long straight shoots which are very suitable for training up pillars or upon rafters in conservatories, where they form grand ornaments in the late winter or early spring months. The most handsome in this respect of all the species is, perhaps, *A. Riceana*. Its graceful slender growths, depending like a Weeping Willow, render it singularly effective for training to a pillar or arch in a conservatory.

Acacias are very floriferous, but they need full exposure to light to insure the thorough solidification of the growth. Plants kept under glass through the summer, where they necessarily have to make their growth under the shade of climbers or a shaded roof, are not nearly so satisfactory as those placed outdoors from early or mid-June up to mid or late September. Without this accommodating nature they are hardly suitable for small houses, for whatever may be their heights described in lists, the plants generally much exceed the proportions accorded them. There is one thing, however, about Acacias that renders them more accommodating than other plants, and that is their bearing cutting well, and this means their being kept fresh looking in moderate sized specimens.

PRUNING.

The best time to prune Acacias is immediately after flowering. The principle, however, to be adopted is laying a good foundation by pinching and attention to pruning in the early stages, which, as most of the plants are raised from seeds, requires an effort, as the ambition of most growers is to get a large and early flowering plant as soon as possible. The plant must be headed early if it is to have a well-furnished base. The strong growth will monopolise all the sap, and so much so as to impoverish the weaker growths, whilst usually the more floriferous succumb. This must be prevented by cutting back the strong growths, and so equalise or distribute the sap, causing, as far as practicable, an equality of growth. The pruning may be to the old wood, but the growth will neither be so free nor desirable as from shoots of the previous year. In fact, when an Acacia becomes old, bare and tall, it is best to discard it altogether, and others should be grown to supplant it.

The pruning in most instances will be confined to shortening strong growths and irregularities, and cutting out weakly and dead wood, so as to have a compact specimen. This, if done as the plants cease flowering, will keep them in useful form for a number of years. They should be kept rather drier after pruning, and when fresh growth is being pushed they may be potted, merely loosening the sides of the ball, and transferring to pots a couple of inches larger, draining well, and in potting making the soil as firm as the ball. Three parts turfy loam of a friable nature, with a third of leaf soil or fibrous peat and a free admixture of sand, will grow them well. Water carefully, and sprinkle morning and afternoon until the roots have taken to the fresh soil, when as the growth advances they will require more copious supplies of water.

In June, as before stated, the plants may be placed outdoors, in a position fully exposed to the sun, but sheltered from winds. The pots should be stood on a concreted bottom or a good thickness of ashes, and be plunged to a little of the rim in that or similar material, allowing space between the plants for the free access of light and air. Copious supplies of water will be necessary, never allowing them to lack, or giving any until it is required, and always affording it so that the soil is moistened to the drainage. In these quarters the plants will make clean healthy growth, ripening the wood perfectly, and when that is effected a full amount of bloom may be expected. In hot weather a good syringing in the evening will be useful in cleansing the foliage and preventing attacks of red spider.

The plants should be housed at the end of September or early in October, assigning them a light airy position in a temperature of 40° as a minimum, and 45° to 50° as a maximum from artificial heat, in which they will flower. An effective display will be assured of what are at least showy plants, and though not as durable as many the sprays are useful in a cut state, the yellow balls or spikes, as the case may be, enlivening otherwise formal arrangements. They are also brilliant for decorative purposes indoors, and are in no way injured, even where there is gas, by a brief sojourn in corridors and halls; of course they cannot well be used in places that have a pale white or yellow ground, but they tell well against a ground of green or blue. Acacias, though of the freest and easiest culture, cannot bear overwatering. If ever the soil becomes sodden and sour the plant will lose its roots, and it will seldom if ever recover.

PROPAGATION.

Propagation is readily effected by seeds, which are best sown as soon as ripe, or they may be kept until the spring, using fibrous loam with a third leaf soil or peat, or the seeds may be sown in sandy peat. Cover about a quarter of an inch deep, more or less according to the size of the seeds, their diameter being a proper depth, and place in a house with a temperature of 55° to 60° artificially, and when up keep close to the glass to prevent drawing. Pot them when they are showing the second leaves, and keep in the same temperature well up to the glass until established; then remove to a cooler house or pit, where the plants can be grown sturdily.

Propagation is also effected by cuttings of the half-ripened wood, which taken off and inserted with a heel, root freely during the summer. Drain the pots well, and fill to within three-quarters of an inch of the rim with peat and sand in equal parts, surfacing with half an inch of sand, making thoroughly firm. Insert the cuttings at once, water well, and stand aside for a short time to dry, then place in a close frame or cover with a bell-glass, shading and watering so as to prevent flagging. They do not require heat, rooting as well or better in a close pit or house without heat. Pot when rooted, and keep in a close pit or house until well established.

VARIETIES.

The number of species and varieties of Acacias that are worthy of cultivation is very great, and a few are named as being particularly good in my own experience. I know many others that are favourites

FIG. 31.—ACACIA OVATA.

with various growers, but as I have not grown them they are not included here. My selection includes *cordata*, *pulchella*, *Drummondii*, *armata*, *diffusa*, *ovata* (fig. 31), *longifolia*, *magnifica*, *grandis*, *verticillata*, *cultriformis*, *dealbata*, and *olavifolia elegans*.—A. G.

FRUIT FOR BRAIN POWER.—According to a recent health report blanched Almonds give the brain the muscle food, and the man who wishes to keep his mental power up would do well to include them in his daily bill of fare. Juicy fruits develop more or less the higher nerve or brain, and are eaten by all men whose living depends on their clear-headedness. Apples supply the brain with rest. Prunes afford proof against nervousness, but are not muscle-feeding. At the same time, it has been proved, says a contemporary, that fruits do not have the same effect on everybody. Some people have never been able to eat Apples without suffering the agony of indigestion, to others Strawberries are like poison.

THE NATIONAL CHRYSANTHEMUM SOCIETY.

ANNUAL GENERAL MEETING.

SHORTLY after the appointed hour of seven o'clock on Monday evening last, Mr. Percy Waterer took the chair at this important meeting. The large room at Carr's Restaurant was completely full, many persons present having to stand throughout the proceedings. Not only were London and suburban Chrysanthemum growers present, but many of the provincial affiliated societies sent representatives to look after their respective interests. The minutes of the previous annual meeting were taken as read, as were the report and balance-sheet given hereunder, these having previously been distributed to members.

REPORT OF THE EXECUTIVE COMMITTEE, 1899.

IN presenting their annual report your Committee feel they can congratulate the members upon a condition of affairs in relation to the Society of a generally satisfactory character. Their exhibitions have maintained their high quality without decreasing in extent, the hold of the Society upon the numerous provincial and foreign Societies affiliated to it is as wide and firm as at any time, the work of the Floral and Classification Committees has been carried out with spirit, the financial position of the Society is decidedly encouraging, the balance-sheet statement for the year showing a substantial balance in hand, while the assets of the Society are of an improved character. Your Committee recommend that the sum of £50 of the reserve fund, now on deposit, be increased to £100.

The three exhibitions held by the Society, although affected to some extent by the incidence of a late spring, and summer so continuously hot and dry as to materially affect the well-being of the plants, yet brought together singularly fine blooms of the Japanese type, though the incurved blooms were scarcely so numerous and refined as in previous years. Still, let the character of the season be what it may, the cultivators of Chrysanthemums rise superior to antagonistic influences, and are always found producing blooms of high excellence. It is not without feelings of regret your Committee note that the incurved, the

reflexed, and the Anemone-flowered types appear on the exhibition stages in decreased numbers, though this fact may not, of itself, justify any apprehension that there is an actual lack of interest in the culture of the varieties of these sections.

The vase class was the leading feature at the November exhibition, and made a most imposing display, arousing a large amount of public interest. The competition was numerous and keen, though some who had entered for competition found themselves at the last moment unable to bring their flowers. The large-hearted liberality shown by Messrs. James Green & Nephew in providing such a considerable number of handsome vases free of charge for the purposes of the class was highly appreciated by your Committee. At all the exhibitions, miscellaneous exhibits, mainly supplied by the trade, afforded features which enhanced the interest of the various displays, and imparted an attractive variety as well.

It is satisfactory to notice that the competition among affiliated societies for the possession of the challenge trophy is maintained with spirit. Still it is desirable more societies should take part in the annual contest. The possession of the Holmes' Memorial cups appears to continue to fire the ambition of growers, and give occasion to close competitions.

Your Committee are under a great obligation to their President, Sir Edwin Saunders, for his valuable special prizes; to the Chairman, Mr. P. Waterer, for his special prizes for an essay on the Chrysanthemum rust, which failed in its objects; and to other donors of special prizes which enable the Committee in a few instances to introduce special features into their schedule of prizes.

A sub-committee have had under consideration the relation existing between the National Chrysanthemum Society and affiliated societies, and having reported that it is desirable certain amendments be made to the privileges enjoyed by affiliated societies, your Committee have adopted the same; and as alterations in the rules are, made necessary, such alterations will be proposed for adoption at the general meeting.

In November last a deputation from your Committee visited Lyons in response to an invitation from the Secretary of the French National Chrysanthemum Society, for the purpose of taking part in an important exhibition of Chrysanthemums; and an interesting account of the proceedings of the same, compiled by Mr. C. Harman Payne, will be published with the annual report, &c. A very hearty vote of thanks was passed by your Committee to the deputation, they at the same time placing on record their belief that the exchange of international courtesies in this and other ways between home and foreign cultivators and lovers of the Chrysanthemum is most desirable, and should be promoted in every possible way.

Audited and found correct { JOHN R. CHOLMELEY.
F. J. BERRIDGE. January 22nd, 1900.

The Chairman in moving the adoption of the report and balance-sheet was very brief. On the whole he considered everything to be quite satisfactory, with the exception that incurred varieties were not shown so well as he should have liked at the November show. He considered the date rather too early for this section, and looked for the time when by increasing the prizes for incurred a good display might be brought together in December. He regretted one omission from the report of the Committee, which had reference to the visit that was paid by the members of the Society to Mentmore last summer. This he characterised as one of the most enjoyable outings it had ever been his pleasure to participate in, not only because of the splendid gardens, but because it had provided the unique opportunity of seeing two Derby winners under one roof. The finances, he was pleased to be able to say, were in a very much better state than heretofore. He deplored the fact that the annual dinner was not self-supporting, and trusted steps would be taken to make it so in this and succeeding years. In furtherance of this object he would suggest the reduction of expenses for professional talent. Mr. Langdon contented himself with being the seconder, and added no remarks.

Mr. Simpson followed, and made some trenchant remarks respecting the services of professional talent at the dinners, and reminded the meeting of the occasion when amateurs were relied upon, and his strictures on them were by no means complimentary. He considered that if the Society could pay over £20 for judges' luncheons they could afford about £12 towards the annual dinner. Mr. Newell also made a few pointed allusions to the dinner, maintaining a somewhat critical tone throughout. Mr. J. W. Moorman, who has on previous occasions been severe in his remarks on the management, had been forced, in view of the changed condition of affairs, to alter his tone, and was of the opinion that though there might, and doubtless were, a few faults to be found, the Society had just reason for self-congratulation, as through various beneficial changes they were improving in status, and were working towards that independence which alone can insure the greatest good being done. Mr. Dean then lucidly explained one or two points in the financial statement. The motion was put to the meeting, and carried unanimously.

The election of officers for the ensuing year was then proceeded with, and in rapid succession the following appointments were made, and in every case without a dissentient voice;—President, Sir Edwin Saunders; Chairman, Mr. Percy Waterer; Vice-Chairman, Mr. T. Bevan; Treasurer, Mr. C. E. Wilkins; and Honorary Foreign Corresponding Secretary, Mr. C. Harman Payne.

Then came the event of the evening—namely, the appointment of a General Secretary, and the members present prepared themselves for something sensational. In this they were not disappointed. The Chairman rose and stated that he had a paper on which there was neither a proposer's nor a seconder's name, and he therefore took upon himself the task of proposing Mr. Richard Dean as General Secretary for the ensuing year. In doing this he spoke of the work that had been done by Mr. Dean in the past, and thought that this should be taken into consideration. He further paid a tribute to Mr. Dean's energy and perseverance, as did Mr. R. Ballantyne, who was the seconder, and in both instances the expressions were well received. Mr. T. Bevan came forward with an amendment in the form of a motion—"That the election of the General Secretary be postponed; and that an advertisement be inserted in the gardening papers for a properly qualified person to fill the post at a salary of one hundred pounds per annum." In supporting this Mr. Bevan made some very serious allegations, and it was easy to see that in doing this he gave himself much pain, but carried it through conscientiously, as he considered it his duty, in the interests of the welfare of the Society. Mr. W. Wells seconded the amendment. There were several speakers, all more or less to the

point, for and against the amendment; but we do not consider it desirable that we should give detailed reports, as some of the remarks were certainly irrelevant, and not always couched in strictly Parliamentary language. Mr. Dean made, as might have been expected, a very strong defence. He spoke deliberately, and was frank in admitting errors and expressing regret, and, as he said, "What more could an English gentleman do?" On being put to the vote the amendment received four supporters only, and the Chairman's proposition that Mr. Dean be elected was heartily carried.

ELECTION OF COMMITTEE.—Upwards of a score of gentlemen were nominated to fill the fifteen vacancies on the Committee, and of these the following were elected:—Messrs. J. H. Witty, 72; J. W. Moorman, 68; D. Ingamells, 67; J. Lyne, 61; A. Newell and W. A. Sturrock, 56; Cuthbert, 51; J. R. Cholmeley, 49; W. A. Holmes, 47; R. E. Reeve, 46; T. G. Swales, 44; J. Brookes, 42; G. F. McLeod, 38; A. J. Foster, 37; and E. Dove, 36.

PROPOSED ALTERATION OF RULES.

The discussion relative to these matters was heated at times, but it would serve no useful purpose to give the names of the participators therein. The results of the voting are shown beneath.

The following amendments to the rules of the Society were recommended by the Executive Committee:—

X. AFFILIATED SOCIETIES.—Subject to the sanction of the Executive Committee, any Chrysanthemum or horticultural society may become affiliated to the National Chrysanthemum Society on payment of an annual affiliation fee of half a guinea, such fee entitling it to the following privileges, subject to the conditions hereafter named:—

To delete privilege No. 1 as follows:—

PRIVILEGES.

1.—To appoint one of its *bonâ-fide* subscribers as a delegate to the Executive Committee of the National Chrysanthemum Society, with power to vote at all meetings, unless otherwise specified.

And the following substituted:—

"To appoint one of its *bonâ-fide* subscribers, who is also a member of the National Chrysanthemum Society, as a delegate to the Executive Committee of the National Chrysanthemum Society, with power to speak and vote on any subject except finance." Carried unanimously.

Notice of amendment by Mr. J. W. Moorman to the foregoing new privilege as follows:—

To delete the words "who is also a member of the National Chrysanthemum Society." Carried.

In the event of the foregoing amended privilege being adopted, to add after "Fellows" in the first line of Rule IX. as follows:—

IX. PRIVILEGES.—All Fellows, members, and delegates from affiliated societies shall be entitled to vote at the general meetings of the Society. Fellows shall be entitled to four passes; members subscribing half a guinea to two passes; and those subscribing five shillings to one pass, to all the Society's exhibitions and meetings of the Floral Committee.

The word "and," and delete the words "and delegates from affiliated societies." Rendered unnecessary by the preceding.

To add the following two new privileges, to be severally numbered 2 and 3:—

2.—"That such delegate be annually elected by the Society appointing him at a properly constituted meeting of such Society." Carried.

3.—“That a copy of the resolution appointing such delegate be sent to the Secretary of the National Chrysanthemum Society, with an intimation to the effect that the appointment was made in due order.” Carried.

To rescind Condition 1 of Rule X. as follows:—

“That the Society’s medals and certificates be awarded only in classes for plants or cut blooms of Chrysanthemums, and that all inscriptions be recorded thereon before being handed to the winners.”

And substitute for it the following:—

“That with the one special exception hereafter mentioned, the Society’s medals and certificates be awarded only to classes for plants or cut blooms of Chrysanthemums, and that all inscriptions be recorded thereon before being handed to the winners; but affiliated societies obtaining the medals of the Society are permitted to purchase one extra medal, which may be awarded to non-competitive exhibits of any kind at their exhibitions, at the discretion of the Judges.” Carried.

These accepted propositions necessitated some slight alteration in the established rules, and these having been formally made the meeting closed.

APPLE HORMEAD’S PEARMAIN.

At the meeting of the Royal Horticultural Society, held in the Drill Hall on January 23rd, Messrs. G. Bunyard & Co., Maidstone, exhibited a small collection of Apples. Amongst these was a magnifi-

FIG. 32.—APPLE HORMEAD’S PEARMAIN.

cent dish of Hormead’s Pearmain (fig. 32), for which the Fruit Committee recommended an award of merit. This variety is comparatively well known, and is described in Dr. Hogg’s “Fruit Manual” as follows:—

“Fruit, medium sized, $2\frac{1}{2}$ to 3 inches wide, and $2\frac{3}{4}$ inches high; even in outline, and roundish. Skin, greenish yellow, becoming quite yellow when fully ripe, and an orange tinge where exposed to the sun; there are here and there traces of thin russet. Eye, partially open, with flat convergent segments, set in a wide basin. Stamens, median; tube, short, funnel-shaped. Stalk, short and stout, with sometimes a fleshy swelling on one side, surrounded with a patch of russet. Flesh, firm, crisp, very juicy, and pleasantly acid. Cells, roundish obovate; axile. An excellent cooking Apple; in use from October till March.”

ASTER SINENSIS.—The double varieties of Asters have long been in the ascendant, and too few realise the value and beauty of the single varieties, which are most telling. One of the best is Aster sinensis, which adds such brightness and grace as to make it valuable as a cut flower, the beautiful pale mauve florets and bright golden disc being most convincing. The habit of the plant is pretty, and it is undoubtedly a welcome addition to the summer occupants of the flower garden. Seeds will soon have to be sown, and anyone on the look out for a good thing cannot go far wrong in ordering.—R. BEAUMONT.

THE YOUNG GARDENERS’ DOMAIN.

BITS FOR THE BOTHY.

TO OUR RECRUITS. (Continued from page 82.)

LEST it should be inferred by the suasive tone of our introduction that we are flaunting the flag in order to lure young men into the ranks, it must be emphatically stated, and distinctly understood, that such is not the case. Volunteers only are wanted, and with these it would be an excellent plan could examination test their fitness for the force. More than once has an anxious mother inquired about gardening as a vocation for her boy, to be answered by another question, asking the reason why gardening has suggested itself. In most cases the reason given is no reason at all, and in some there is every reason for advising that the boy’s tastes and talents should be directed into another channel, to which his inclinations trend. At this stage the parental element cannot be wisely excluded from this paper, hence no apology is needed for bringing mothers into council to prevent a mistake—a life’s mistake, maybe, which is the most serious mistake of all. Where advice is sought upon this matter more or less suspicion attends the case. The youth with an inspiration for gardening is, willy nilly, an embryo gardeuer. Nature herself has saved anxious parents all trouble in worrying about what to do with their boy.

As it is, all sorts and conditions of boys are recruiting for the garden; and, as it is, the matter must be dealt with. Parents may be to blame, boys may not be blameless, but circumstances which perhaps neither can control are the biggest sinners of all. It is the writer’s earnest desire to help all to see and to feel such things as might otherwise pass their understanding, and consequently keep them as drones in the human hive. Some youths that have been thus pressed into the service now occupy high positions in the gardening world, and there is no reason why others should not do the same. Absence of past passion is no hindrance to future love. The lad whose love for gardening is an inspiration is, of course, the boy after one’s own heart; yet in his inexperience are openings for advice, for good performance does not always follow on great promise; “Temptation hath a music for all years,” and he in falling from his high estate may lose his birthright in the bog of blighted hopes. Comparisons have necessarily been drawn, henceforth recruits of all sections will please “fall in” together.

Attention! Eyes right—on your work. Anyone looking back now had better “fall out” and don the scarlet coat, the navy blue or whatever colour or career he has a lingering regard for. None? All going in for gardening; then may you all come out gardeners in the fullest sense of the term. Orders of the day are make the most of your time. At a rough estimate the drilling process occupies about ten years. It is a long time to look forward to, but an exceedingly short time to look back upon. To reconcile the optimistic eyes of youth with the pessimistic spectacles of age we may add these periods together, divide the sum by two, and the balance of time struck is truly little enough for the great work in hand. All work needs recreation. In this recreation lays many, if not most, of the secrets of success. This will be explained in due course. In the first place the importance of uniting body and soul in work cannot be overestimated or too strongly impressed. (A body without a soul is like a flower without scent). You do not see how they can be separated, but it is easily accomplished and frequently happens. Our stokehole boy is a good illustration; there he is, in the stokehole, so far as his body is concerned, but his soul loveth cricket, and that it is away at the cricket is very palpably evident by the way in which he holds the fireshovel at “cut to leg,” playing imaginary balls, and very probably, though it is said very reluctantly, he will have to make a run elsewhere, and take his innings on fresh fields and pastures new.

The soul must go into the work—“He who follows two hares will be sure to catch neither”—even to the meanest work a boy is put at, or it will amount to mere drudgery, and the performer will be a drudge. In reality there is no mean work that is done for a useful or necessary purpose. The boy who sweeps the boiler flues, stokes the fire, or scrubs out the houses in the very best possible manner, is doing as much in his way as any of our great generals at the front are doing in their way. Like most campaigns, there is much hard fighting to be done, and the moral effects dependent upon the earlier battles of life are many and far reaching. “Peace hath her victories no less renowned than war.” The most daring thing is often that of daring to do right, and to do that at the right time is to double its value. There may, in some instances, be no disgrace in defeat, but there is always the danger of being made a prisoner—for life.

“Free, yet in fetters held till his last breath;
Gyves that no smith can weld, nor rust devour.”

There is a host of bores, and particularly crafty ones, to overcome; but they can and will be overcome if our young warrior wills it. During working hours they love not the master’s eye, but spring up in all directions behind his back, and the bothy breeds them as fast and plentifully as the old fashioned bothy used to breed blackbeetles. As previously shown, the favourite form of recreation seems consciously or unconsciously to permeate our work; how necessary it is, then, that it should be made subservient to it! Manual labour demands, or should do, mental recreation, consequently nothing could fit better into a recruit’s training. It is a paradox,

however, peculiarly British that much of this so-called recreation is characterised by an exhibition of physical force. Some say they find hard work easier than study. They get terribly bored at the start, and of all the bores that lurk in the body this is the biggest bore of the lot. Many a lad contemplates with almost horror the idea of placing himself under restraint during his hours of absolute freedom. He knows that he should do so, for young gardeners are far from being deficient in common sense. But these bores are for ever showing a flag of truce, so they are temporised with. Something or other prompts putting off the settlement to a more convenient season, when a grand attack will be made with all the artillery of splendid designs and elaborate plans. It is magnificent, but it is not war. Fight 'em at once, boys; and fight 'em to a finish. You don't exactly know how to begin. To show you how to begin and how to finish will be both a pleasure and a privilege to—
THE OLD BRIGADIER.

(To be continued.)

FRUIT FORCING.

Vines.—*Early House.*—The Vines in flower should have a temperature of 60° to 65° at night and 70° to 75° by day, but Muscats require 5° more both day and night. A somewhat drier atmosphere, secured by freer ventilation rather than withholding moisture, favours the development of the organs of fructification. Care, however, must be exercised in ventilating during severe and sharp weather, avoiding an inrush of cold air, which chills and stagnates the growths, producing rust in the berries and crumpled foliage. A genial atmosphere must be insured by keeping the floors sprinkled two or three times a day in bright weather, but occasionally only in dull periods. Stop the laterals below the fruit at the first leaf, and keep those stopped to one joint throughout the season, but those above the bunch may be allowed to make two or more joints, provided there is space for the full exposure of the foliage to light and air.

Vines Started at the New Year.—The Vines are in leaf and showing the fruit at the points of the shoots. Do not hasten disbudding, but perform the operation gradually, removing the weak and least promising growths in the first instance, then give further attention when it is seen which shoots are likely to give the best bunches. One cluster on a spur is as much as is likely to finish satisfactorily, but judgment must be exercised. When the spurs are widely distant along the rods two shoots may be left on each spur, but only one must be allowed to bear fruit. Weak Vines may be allowed more space so as to secure stouter wood, larger and plumper buds, and better bunches in the following season. When the growths are advanced about two or three joints beyond the bunches their points may be pinched off, this being effected when the leaves at the stopping joint are about the size of a shilling. Give the needful protection to outside borders, keeping the soil from becoming frozen.

Vines to Afford Ripe Grape in July and August.—The Vines must now be started, and as they break more evenly and strongly when assured a moist genial atmosphere, damp the rods two or three times a day in bright weather, and sprinkle other surfaces. Occasional damping only will be necessary in dull weather. A temperature of 50° at night, 55° by day, and 65° from sun heat is suitable until the buds begin to move. Bring the inside border into a thoroughly moist state, but not saturated condition, by repeated waterings with tepid water, and if the Vines are weak and the soil open afford a supply of liquid manure after it is watered sufficiently for healthy growth. The soil will then retain most of the manurial elements, and they will pass into an assimilable form, or such as is available for taking in by the roots, and will accelerate root activity as well as supply nourishment. The outside borders should have sufficient protection to prevent chill.

Late Houses.—The Vines being cleared of the Grapes early in January, then pruned, dressed, and the structures thoroughly cleansed, afterwards removing the loose surface soil, and supplying a top-dressing of fresh loam with an admixture of fertilising ingredients, they will be ready for starting whenever desired. The varieties taking a long time to grow and mature perfectly must be started in good time, so as to give them the benefit of the summer for developing and maturing their crops. A start should be made without much further delay, as it is essential to the perfecting of the Grapes, especially those subjected to the highest cultivation, that the Vines be started so as to have the crop perfectly finished by the middle of September. Strong rods should be brought into a horizontal position or lower, and a good break secured by maintaining a genial condition of the atmosphere, and syringing the Vines occasionally in dull, or two or three times a day in bright weather. A temperature of 50° to 55° at night and on dull days, with 10° advance from sun heat, will be sufficient until the buds break, then allow 5° to 10° more by day, husbanding the sun heat by early closing, but losing no opportunity of ventilating freely in the

early part of the day, so as to insure sturdy growth and well-developed stout foliage.

Ripe Grapes.—Avoid fire heat as much as possible in the Grape room; but the cold weather necessitates recourse to constant firing, and moisture is apt to be drawn out and deposited on the cooler surfaces of the Grapes. This sometimes results in "spot," both with and without fungal growth, for it is certain that without the moisture the fungoid germ could not develop, and their germinal tubes not enter the tissue of the Grapes until the cuticles were weakened, if not actually ruptured, by the contact and continued presence of the moisture. A little air will prevent such accumulations of water on the berries, and the Grapes will not shrivel unless the evaporation be excessive and the temperature high. An equable temperature of about 45° is most suitable, and the less light the Grapes receive the longer will they retain their colour. As the water in the bottles diminishes it should be replenished with clear soft water, taking care to avoid spilling any or allowing drops to fall on the Grapes.

DYSENTERY.

SHOWERS of sleet and snow have been of frequent occurrence for some weeks, and although not much frost has been registered, the temperature has been low. This has had the effect of confining the bees to their hives. The first fine day after a period of inactivity will cause the bees to leave the hives in great numbers, and should the weather suddenly become dull and cold many will become chilled and will be unable to return to their hive. A cleansing flight at this season is necessary for the welfare of the bees. Bee-keepers recognise this fact when they observe the faecal matter which will be much in evidence on the outside of the hives, or wherever the bees alight.

It must not be taken for granted that the bees are suffering from dysentery when these spots are first seen. If it is of a pale yellow or chocolate colour it is the ordinary excrement, and if they have not taken a flight for several weeks will usually have a disagreeable smell. If the weather is favourable and the bees are healthy the majority of them will return to their hive.

If a stock is affected with dysentery it is much more serious. Fortunately this disease is easily detected by a close observer. The matter voided by the bees will be found to be much darker in colour; in fact in bad cases it will be nearly black. The bees from a diseased colony will be unable to fly many yards from their hive, while the floorboard and everything within a few yards of the hive will be discoloured with the unpleasant smelling excrement. If the combs are examined they will also be found in the same condition. This is never observed in a healthy stock. The bees, too, will be reduced in numbers, many of them being swollen, and only having sufficient strength to crawl to the alighting board; or if they take wing they are not able to fly more than a few yards, and rapidly become chilled on the cold surroundings.

Bees observed in this condition are supposed by some bee-keepers to be suffering from a distinct disease known as dropsy. After, however, carefully examining many stocks thus affected, we have no hesitation in pronouncing it dysentery. Owing to various causes this disease has been more prevalent since the advent of the modern frame hive than it was when the majority of the bees in this country were kept in the homely straw skep.

CAUSES OF DYSENTERY.

There are several causes of the disease. Feeding stocks late in the autumn, so that the bees have not time to seal their stores, is one of the most frequent. For this reason we always advise bee-keepers to feed their stocks for winter as soon as the honey harvest is over, as it is then sealed at a rapid rate when the temperature is high. We cannot do better than imitate the bees in this important matter. If they are left to themselves, and are not robbed of their stores, the honey is sealed over as soon as it is in proper condition. This takes place during the long days of summer, and will account for the bees being less affected with this disease in straw skeps, as the stocks intended for wintering purposes usually had all their natural stores left in the hive.

Dysentery may also be caused by keeping the bees in a damp, cold hive, where they cannot be expected to do well. Our attention was called to a hive of this description not many weeks ago. The first fine day afterwards we carefully removed the bees and combs that were not mouldy into a dry hive, a cake of candy being placed directly over the cluster. Extra coverings were also used, with every prospect of the bees doing well in the future. Warm weather will work wonders with a colony if it is not too much reduced in numbers. A dry hive, warmth, and good food will do the rest. Prevention, however, is better than a cure.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Employment in Australia (*G. C., jun.*).—Your best course will be to procure the "Horticultural Directory" from these offices, price 1s. 3d., post free, and write to the several Australian nurserymen named therein. They would certainly reply to you if they were in want of an assistant with a knowledge of the English trade.

Evergreen Creeper for a High Wall with an East Aspect (*W. G.*).—The best of all evergreen climbers for quickly clothing a wall, especially one 30 feet in height and somewhat sheltered by trees, is the common large-leaved Irish Ivy, *Hedera helix canariensis*. Plants in pots are the most satisfactory, as they travel and plant quite safely even when 6 feet in height or more.

Lime and Manure for Tomatoes Under Glass (*A. Z.*).—The lime and manure recommended to "R. F." for Tomatoes, in our issue of February 1st, answers well for cultivation under glass. Salt is named in relation to lime, and we wish you to observe that the lime ought to be applied and dug in some time in advance of using the salt, but the salt left on the surface. It is not generally advisable to use salt and lime at the same time, but we advise kainit instead of salt, and so escape chloride formation.

Treatment of Asparagus (*Idem*).—It is a well-known fact that cutting is a weakening process. We have noticed that young Asparagus plants push two growths in a season—the first relatively weak, and another, about midsummer or soon after, comparatively strong; and these monopolise the vigour, and form correspondingly fine heads for developing the following season. It is a good practice, therefore, to allow the weak grass to grow to the end of cutting time, say June 20th, and then cut away, leaving the stronger only to each rootstock. Some growers cut off the very small shoots after they have developed, and thus cause a second growth to be made earlier, and at the end of the cutting season pull out any small shoots, leaving only the strong to grow. The coat of stable manure early in spring and the two dressings of salt, about $\frac{1}{2}$ lb. per square yard, will be excellent. A considerable advantage may be derived from the use of Peruvian guano, about 2 ozs. per square yard applied early in April, and repeated in about six weeks, taking care not to use it over the heads, but between the rows and plants.

Lilium giganteum (*Tyro*).—Let the pots be twice the diameter of the bulbs, the soil half turfy loam, the remainder equal parts of peat, leaf mould, and decayed manure rubbed through a sieve, adding a handful or two of sand, all to be well mixed; embed the bulbs in sand, and first cover with soil 2 inches below the rim of the pot. Bury the pots in cocoa-nut fibre refuse or ashes in a cold frame or other cool place. The plants will grow in frames, light greenhouses, or outdoors in summer.

Improving a Lawn (*C. H. G.*).—In dry weather towards the end of March scratch up the lawn, breaking the surface soil with a sharp-pointed iron-toothed rake. This must be carried out when it can be done best, not when the ground is baked hard; still it must be somewhat dry. If you can further spread on some sifted soil that you may in the meantime collect for filling up inequalities, so much the better. Then sow freely some renovating lawn seeds, sprinkling a little soil over them if you have any; if not, work them in as well as you can with a rake, and draw a roller over the surface or beat it down with a spade. If birds do not eat the seeds, and they may be prevented by stringing cotton a few inches above the surface, you will soon have a green lawn, and it may be kept so by judiciously mowing, not cutting too closely the first three times, or several of the young Grasses may be destroyed. Bonemeal and the advertised manures are good for lawns, applied at the rate of an ounce or two to the square yard in showery weather.

White Worms in Poultry Manure (*Puzzled*).—The minute white worms are certainly not wireworms, at least we have never found them in poultry manure, but are members of the same order as the earthworm, *Oligochaeta*. There is little doubt that they attack the roots and root stems of Clovers, Vegetable Marrows, and other plants. We have known them injurious to Currant bushes by destroying the tender rootlets; Apple trees on the same ground not being affected. We should not use the manure for fruit trees amongst which vegetables are grown until treated with lime or gypsum. Our plan with such stuff, for we have used poultry manure extensively in fruit and vegetable grounds, was first to disinfect it. 1, Spreading rather thinly and sprinkling on the manure air-slaked chalk lime, a foot thickness, having about an inch of lime placed on it, then the heap was turned two or three times and left for a day or two, always before violently heating spreading on the land and digging or pointing in. 2, Throw the manure into a heap, sprinkling, if dry, with a solution of sulphate of iron, 1 lb. in 10 gallons of water, and cover the heap with gypsum. Allow this to heat, and when quite hot turn inside to outside and top to bottom, again covering the heap with gypsum, and in about a week again turning and mixing, keeping after this so thinly as not to heat, or applying at once to the land.

Rose Gloire de Dijon (*F. F.*).—The appearance of the leaves suggests that the wood has not been so well matured as is desirable, and possibly the growths were overcrowded during the summer, still if the wood is strong enough and moderately firm, flowers will probably follow in due time. You must remember that no Rose can do what is expected of it if the growths are allowed to be infested with insects. Your greenhouse ought to have been fumigated long ago, and the Rose well and frequently syringed to keep it clean. If there is nothing to prevent fumigation fill the house with smoke from tobacco or good tobacco paper on two consecutive nights, then syringe the plant thoroughly with an insecticide. If fumigation cannot be done syringe forcibly and repeatedly. The advertised insecticides, if used according to the directions that accompany them, will answer the purpose for which they are prepared. If the stem outside the house has been exposed to the weather the plant may have sustained injury. We have many times stated that such stems should be protected with hay bands. Any that may be still exposed should be covered at once, as when growth starts under glass a sharp spring frost may stop the rising of the sap through the exposed stems outside the house.

Brown Spots on Clematis indivisa Leaves (*C. D., Kent*).—There were found mycelial hyphae in all the browned parts of the leaves, which, with some outgrowths from the younger blotches, indicate an attack by the rather uncommon Rose mould, *Peronospora sparsa*. It grows, as a delicate grey mould, on the under side of the leaves of Roses, in conservatories, but we have found it on a few woody plants under glass in addition to Roses, *Clematis indivisa* being one of them. The leaves become spotted with brown, and soon shrivel. This is due to the growth of fungal mycelium in the tissues of the leaf or leaves, which spreads from a centre of attack. Being wholly internal in its growth no outward dressing can do more than prevent the spores germinating or the disease from spreading. The endophytic nature of the parasite may account for "some mildew remedies" not having effect. We should try the preparations in powder of sulphate of copper, such as anti-blight, fostite, and strawsonite, applying lightly and occasionally by means of a bellows apparatus. As the leaves are smooth there is some difficulty in getting the powder to adhere, therefore many use the article in solution, applying with an atomiser or sprayer, merely coating the growths with the finest possible film. We found this, after removing all the affected parts and burning them, effective, air being given very freely and the atmosphere kept rather dry, for the fungus thrives best in a close moist atmosphere, and on rampant, succulent growths, the drier conditions tending to render the plant more resistant.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (C. B. A.).—1, *Asplenium pubescens*; 2, *Onychium japonicum*; 3, *Polystichum angulare proliferum*; 4, *Scolopendrium vulgare cristatum*; 5, *Cyrtomium falcatum*. (S. S.).—1, *Thuiopsis dolabrata*; 2, *Berberis Darwini*; 3, *Garrya elliptica*. (W. M. W.).—1, *Zygopetalum Mackayi*; 2, *Justicia speciosa*; 3, *Eucalyptus globulus*; 4, *Cupressus macrocarpa*; 5, *C. Lawsoniana*; 6, *C. L. erecta viridis*.

BASIC SLAG.

OWING to the drop in the price of grain—a drop which makes that grain-growing a most unprofitable and heartbreaking process—and owing also to the fact that the question of labour is a burning one, there is naturally a tendency to lay down more ground as permanent pasture. Some of the land is well adapted for this plan, and given a really good selection of proper seeds in a few years the result is satisfactory.

In taking a railway journey or a bicycling tour of any length, how many different kinds of pasture we come across, and we are not the first, nor shall we be the last, who have noted with sorrow the indifferent management of a great part of that grass land. Of course, we are well aware there are acres upon acres of splendid grass which practically “manages” itself, and it would take a wonderful concatenation of adverse circumstances to spoil it. We remember in the seventies seeing park grass in Northumberland which let for £7 per acre. We never quite saw how that rent was afforded: but it was given, and the north country farmer is not a baby. But enough of this super-excellent pasture; what of the great middle class and the moderate? We all admit there is room for improvement there. True, you can never make silk purses out of sow's ears, but you might make a good leather wallet.

The first essential point is to find out what is lacking in the constituency of the soil. There may be various valuable ingredients lying dormant, and they want just the right sort of fillip to put them into full working activity. Sometimes exchange of stock will prove beneficial; sometimes lack of drainage is the great need. All sorts of applied fertilisers mean an outlay in hard cash, and generally in the economy of a farm it is only the arable crops that get a dressing; this because they show the immediate benefit, and also as there is an idea that the improvement by stock suffices for pasture.

Of late years a new material has come much into vogue—it is the outcome of modern science—a waste product of a great manufacture and a waste product of great value. We refer, of course, to basic slag. Anyone who reads the agricultural papers will have seen the discussions for and against this manurial agent. Like all new things it finds enthusiastic partisans and emphatic detractors. Some people go red hot into any new scheme, and therefore generally burn their fingers. Others hasten slowly, and it is their opinions that ought to carry weight. We find every season there are fresh adherents, and these among men who know what they are about.

We were glad to read in the Royal Agricultural Society's Journal a most favourable report of the basic slag that had been submitted to analysis. Dr. Voelcker says for the year ending December, 1899:—“Basic slag has undoubtedly been used more generally and often to much advantage, more especially on poor heavy land pasture. When first introduced as a manurial article, the greater part of the basic slag produced in this country was sent abroad, but I am informed that quite two-thirds of the out-turn is used here. At the same time there has been a steady improvement both as regards the quality of the material supplied, *i.e.*, its richness in phosphoric acid, and also in respect of the fineness of grinding, a most material point which should never be overlooked. From time to time I have felt it right to alter the terms of our recommendations to purchasers of basic slag, each time in an upward direction; and while 14 or 15 per cent. of phosphoric acid and a fineness of 70 per cent. were not long ago all that could be demanded, a good quality sample will now give 17 per cent. or over of phosphoric acid and a fineness of 80 per cent.”

This seems to us a good testimony as to the character of the article to be purchased. Now a little as to its use. First, what does basic slag contain?—phosphate and lime, both unrivalled as dressings for

grass land. But you say we want potash and nitrogen as well. Wait a bit. We spoke earlier of dormant forces in the land which want very little persuasion to become active. It is always well to use the material that is at home. "Far sought, dear bought." Basic slag has this wonderful rousing power—it liberates the natural potash if present in the soil, and also breaks up humus, releasing the nitrogen, thus making them gratuitous but valuable elements of fertility assimilable by the plant roots, so that basic slag may be applied with great benefit as long as the natural store of potash and humus holds out.

If the soil should not contain nitrogen and potash it is well to apply them in addition to the slag, bringing up the whole of the manurial value to 20s. or 30s. per acre. This has been found to be more effectual than double the value of farm manure. Here is the testimony of a farmer: "I have an 18-acre field of seeds that had 5 cwts. per acre of basic slag in October 1897-1898. It was grazed the first year, mown this year, and is now full of Clover, and kept green and fresh all through the hot weather; it is being grazed now (November) and will do to graze another year. As soon as it is clear of stock it will again be dressed with 5 cwts. per acre."

This is creditable for the last hot, dry summer, when fresh herbage was hard to find. Not only is the quantity of the grass increased, but there is a wonderful difference in its feeding value. The cost of this fertiliser is about 42s. per ton, in some cases rather less, and as the quantity used is generally about 5 cwts. per acre, the expense is not heavy. Experiments are being carried out to decide whether healthy roots could not be produced as well as good grass by the use of this tillage.

Of course the best time for application to grass land is *now*, when the winter rains have a chance of washing the fine powder into the soil. The finer the powder the better. A still calm day should be chosen, and it would be of course the best plan to drill it on the land, previously watering it. The slag, good as it is for the land, is most injurious to human beings, and all risk must be minimised as much as possible. The men should be instructed to guard nostrils and mouth with folds of muslin. This must be insisted on. This is a case like many others where precautions are necessary, but with well wetted slag and the exercise of common sense, no danger need be apprehended.

We begin to see there is really nothing "waste" in the whole scheme of creation. Was it not Lord Palmerston who defined "dirt as matter in the wrong place?" We are gradually using up all bye products of our manufactures. We have been, and still shall be, a long time in learning all these things. The last twenty years we have made vast strides. We have had many youthful theories upset, and many new doctrines put in their place. This is essentially the age of the practical chemist, who, by patient perseverance, is wresting from Nature her deeply hidden secrets.

WORK ON THE HOME FARM.

The lambing season has now commenced, and we see in many places newly made folds and pens ready for use, if not already occupied. The greater profit gained by early lambing and the sale of fat lambs has induced many farmers to put forward the lambing season by a month. There is more labour and trouble, also a little more expense in extra food, during the spring; but early sale of lambs and gradual relaxing of the strain upon pastures and cake supply soon make full compensation. So far the ewes are healthy, but it is early to boast.

The weather is mild, and still very wet; much flood water and snow remain visible, and there is not much land in the country dry enough for the reception of seed grain. Early sowing, as we have lately remarked, is advisable, but the work must be done under suitable conditions. Barley is especially fastidious as to a proper seed bed, and we had better wait for March winds than muddle the seed in. Though the land is too wet for working fallows, there is plenty for the horses to do. Sheep are marching rapidly over the Turnips, and the folds have to be ploughed as soon as they are vacated. Seed fields that have been reserved for the Oat crop must also be ploughed without further delay. Such fields have been very useful for the ewes, but must now be spared if a good corn crop is to result. The land would have been better ploughed before Christmas, but the bit of pasturage was tempting.

Land that was ploughed deeply for Potatoes about Martinmas must be worked down at the first opportunity, and then ridged up for planting. Even if it is a little wet it would be better in the ridged state, as it will dry more quickly, and also be more open to frost, besides which there is the gain in having got one piece of work done. Fat beasts and sheep are selling well, especially the former, but butchers complain that they kill very badly, and are short of suet; they blame the absence of good Swedes, and are no doubt right. We fancy that decorticated cotton cake in moderate quantity added to the other artificials would assist good feeding, but yardmen do not like its hardness.

THE IMPROVEMENT OF LAND ACT.—The Board of Agriculture desire to call attention to the provisions of the Improvement of Land Act, 1899, which came into operation on 1st January, 1900. This Act has been passed with a view to give increased facilities to owners of land desirous of carrying out agricultural and other improvements with the aid of borrowed money. With this object the new statute amends the Improvement of Land Act, 1864, and other Acts authorising the creation of rent-charges for the improvement of land. Under the new Act one of the provisions provides that the maximum period over which rent-charges authorised after the commencement of the Act may be allowed to extend is forty years. It must not, however, be assumed that the full term will always be applicable. By another provision, the land charged with the payment of the rent-charge may be land other than that which is directly improved, provided (a) that such other land is shown to the satisfaction of the Board, by statutory declaration, to be held for the same estates or interests, and to be either subject to the same encumbrances (if any) or to be free from encumbrances; and (b) that, in the opinion of the Board, such other land may properly be included in the charge.—("North British Agriculturist.")

FARMERS AND STOCK-KEEPING—EXAMPLES OF WHAT MAY COME HIS WAY.—A fortnight ago we were discussing the question of farmers and showing, and I heard a story a few days ago showing that ignorance in the quality of the stock reared may be a source of loss. This spring a fancier sent off a setting of eggs for 4s. 6d. to a certain farmer. He was asked in the autumn for a cockerel or two more than he could supply. He remembered the farmer to whom he had sold the eggs, and went over to see if there were any good birds amongst them. The farmer's wife informed him that all the cockerels had been sent off to the market the week before—all except one which escaped. This one was packed off, as I understand, without the fancier seeing it. It was sold for 4s. 6d., and eventually it took the cup at the Palace in a certain class. I also heard of a farmer who had a nice lot of pure-bred birds, and a fancier called in and offered £5 for his pick. The offer was accepted, and the bird chosen brought in a fortune to the fancier. I would not suggest that £5 notes lie hidden beneath every pure-bred bird; but certainly, if farmers go in for any particular breed they might as well, to say the least of it, know the special points of the breeds they go in for, even though they have no intention of exhibiting. It would be interesting to know exactly what it costs a farmer with plenty of land to rear chickens up to six months old, and what arrangement would be considered a paying one for him to make to bring up chickens after they have left the hen or the foster mother.—("Farmer and Stock-breeder.")

SOUTH AFRICAN HORSE SICKNESS.—Much more to be dreaded than glanders is the "sickness" which about this time of the year, usually a little later, breaks out over a large portion of South Africa. British veterinary officers have patiently investigated the disease years and years ago, and Mr. Hutcheon and other veterinarians in the service of the Cape Government have continued their researches without ascertaining the cause. It is most rapid and fatal, and it is to be hoped we shall soon hear of weekly consignments of a thousand or two of Australian horses at the least, to take the place of those which will inevitably die. From my own experience, I should expect quite half the number to succumb before the conclusion of peace. I also anticipate a steady and continuous rise in the price of horses in that country, and would point to the fact that they cannot be quickly replaced, and therefore as many good mares should be stinted this spring as each owner can arrange for. The horse sickness has all the appearance of poisoning, so rapid is it in its effects. An animal which, to all appearance, was well overnight, is found next morning blowing like a case of congestion of the lungs: heaving flanks, distended nostrils, great distress and collapse, death following before sundown in most instances. The few which live remain immune for life, and are much valued as "salted" animals. Some seem insusceptible to the disease or less so than others, otherwise the continent would be clear of horses altogether. No medicines appear to have any good effect, but a serum has been employed which is thought to give a certain amount of immunity. It is probable that the horse sickness, like the malarial fever of man, is due to the bite of some poisonous insect. To change the fauna of a country is too much to hope of any government, and while the mosquito infects men, and some as yet unidentified creature poisons horses we can only hope (says a writer in "The Farmer and Stock-breeder"), to blunder upon some prophylactic in the astounding manner of our forefathers, who discovered specifics for certain diseases whose causes they had not ascertained.

BARR'S SEEDS

OF FINEST SELECTED STRAINS AND TESTED GROWTH.

NOVELTIES & SPECIALITIES FOR 1900.

Amaryllis, Barr's Choice New Hybrids, saved from a magnificent collection. Per packet, 2/6.
Aster sinensis, A lovely single Aster, with large handsome flowers of a delicate mauve with yellow disc, bushy, branching habit, ht. 15 in. Per packet, 1/- and 1/6.
Candytuft, Barr's Giant White, very large spikes of snowy white flowers. Per packet, 6d. and 1/-.
Celosia plumosa, Barr's Choice Mixture, handsome feathery plumes. Per packet, 6d. and 1/-.
Lantana, Barr's New Dwarf, a mixture of brilliant colours, charming as a pot plant. Per packet, 1/6.
Lupinus arboreus Snow Queen, a pure white Tree Lupin, fine novelty. Per packet, 1/- and 1/6.
Mignonette, Barr's Covent Garden Favourite, the finest Mignonette for pots or borders, deliciously fragrant. Per packet, 6d. and 1/-.
Nicotiana sylvestris, a fine white-flowered Tobacco with handsome foliage. Per packet, 6d. and 1/-.
Petunia, Barr's Superb Giant, the largest and handsomest of all the Petunias, immense flowers of rich and varied colours. Per packet, 2/6 and 3/6.
Phacelia campanularia, one of the most lovely blue flowers in cultivation, height 8 in. Per pkt., 6d. and 1/-.
Poppy, Empress of China, snow-white single flowers, with a fringed margin of crimson-scarlet. Per pkt., 6d.
Poppy, Shirley, "Long Ditton" extra selected strain of this beautiful Poppy. Per packet, 1/-.
Rose, Miniature Fairy, dainty little semi-double flowers of various shades, blooms first season. Per pkt., 6d. & 1/-.

BARR'S SEED GUIDE contains a Select List of the best Vegetables and the most beautiful Flowers for Garden and Greenhouse. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. Sent free on application.

Messrs. MERTENS & CO.,
 3, CROSS LANE, LONDON, E.C.

No. 1025.—VOL. XL., THIRD SERIES.

APOLOGY.

To MESSRS. SUTTON & SONS,
 Seedsmen, Reading.

Gentlemen,

We extremely regret that in our Catalogue we should have infringed the Copyright of your "Amateur's Guide in Horticulture" by having used two of your original pictures of your vegetables, and making use of paragraphs of your text.

We acknowledge that we have thus laid ourselves open to legal proceedings and a serious penalty, and we offer you our apology for what we have done. We also undertake that we will not in future infringe your Copyrights, and we will forthwith surrender to you all Catalogues or Circulars in our possession containing prints of the blocks and paragraphs, together with electros, negatives, and photographs of the illustrations complained of.

We desire to thank you for your generous treatment in not having taken legal proceedings against us to enforce your rights, and we authorise you to publish this letter in such a manner as you may think fit, and we engage to pay all the legal and other expenses you have been or will be put to in the matter.

Yours faithfully,

(Signed) PENNELL & SONS,

Seed Merchants and Nurserymen,
 Lincoln.

29th January, 1900.

APOLOGY.

To MESSRS. SUTTON & SONS,
 Reading.

Gentlemen,

I much regret that I have infringed your Copyright in two illustrations taken from your "Amateur's Guide," by making process blocks, engraving them with my name, and printing them in Messrs. Pennell's Book of Seeds for 1900.

I wish to state that as I made the blocks from photographs supplied to me the infringements were quite unintentional on my part.

I beg to offer you my apology, and at the same time my thanks for your consideration in refraining from enforcing your rights, and I authorise you to publish this acknowledgment in such manner as you may think fit.

Yours faithfully,

Ulverston, (Signed) W. HOLMES.

February 2nd, 1900.

LONDON FERN NURSERIES,

LOUGHBORO' JUNCTION, LONDON, S.W.—Stove and Greenhouse Ferns, large and small, in var., Aralias, Greivilleas, Cyperus, Ficus, Ericas, Palms, Dracenas, Aspidistras, Roses, Epacris, Solanums, Azaleas, Carnations, Cyclamen, Primulas, Marguerites, Crotons, &c. Trade, send for Wholesale List. Special Retail Catalogue, free.—J. E. SMITH.

WEST'S PATENT GARDEN SPECIALITIES.

WEST'S PATENT Vapourising Fumigator

Best and Cheapest, for being made of brass and zinc will last for years. The stove only requires a little spirit to saturate the asbestos, so may be used thousands of times without wick or further trouble than filling it. Price 6d. complete to vaporise up to 2500 cubic ft.

"WEST'S EXTRACT OF NICOTINE," is guaranteed pure Nicotine and is even cheaper than the compounds that are only chemical substitutes for Nicotine (compare prices), 7d. per air-tight sealed bottle of 1000 cubic ft.

"SUNPROOF" SHADING in 6d. lb. tins ready for use, to be mixed with cold water. Guaranteed to be perfect in all respects and the cheapest shading that can be made.

For particulars of West's patent "Ivory" Plant Labels, Soft Metal Tree Fasteners, S.M. Clips, Wall Nails, Plant Stake Grips, Plant Pot Cocks, Insecticides, Fertilisers, Canes, Sticks, and ALL GARDEN SUNDRIES of every description see Illustrated Catalogue, post free.

Samples free, postage for samples and goods extra. All goods made on the premises by C. E. West, so send direct to the Manufacturers.

Gratis, "Orchid Culture," 3rd Edition, postage 2d. Gives full particulars of the cultivation of Orchids.
THE LEEDS ORCHID COMPANY, ROUNDHAY, LEEDS

Journal of Horticulture.

THURSDAY, FEBRUARY 15, 1900.

The Journal of Horticulture can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 12, Mitre Court Chambers, Fleet Street, London.

TURNING MOVEMENTS.

AS we press onward in our various spheres, each striving with might and main to carve out of the rugged road of life a course which will lead us to some envied goal, most of us, I trow, often spend a few moments in surveying the world's great stage, and noting the ever changing tactics of the players. The battle of life should then be as an "open book," in which we may read that which is spread out before us, but can only hazard a conjecture as to what is to follow.

To all who thus periodically take their bearings one fact must, I think, stand out clearly—viz., the restless activity which prevails in all quarters. Education, rapid means of communication, and the marvellous development of the Press, have so sharpened men's wits, that success in any walk of life can only be maintained by continually changing our methods, and adapting them to the needs of the hour. The individual, or nation, who tries to pursue a straight onward course, without grasping the significance of the changes which are continually taking place, must sooner or later meet with a severe check, which, fortunately to the stout-hearted, would only be the signal for reform—reform in bringing both our weapons and methods up to date. The pendulum of scientific discovery is continually on the swing; sometimes it gives to the aggressor the advantage, at others to the defender. The straight onward course in attack must then be put aside when facing the foe and strategy resorted to, in order to effect a "turning movement," and thus attack the enemy—or the difficulty—at the weakest point.

The noble and heroic efforts of Britain's sons in that far off land of boundless possibilities are watched to-day with breathless interest by millions in this sea-girt isle; not with fear and trembling, but with confidence in the energy, adaptability, as well as grand courage of our "empire's defenders." These same qualities are needed in every walk of life, and to those engaged in the peaceful art of gardening they are in a degree as necessary as to the dashing warrior, for the gardener assuredly has

enemies enough to fight—foes which need restless energy, scientific guidance, and undaunted will to overcome.

Let me now cite a few instances which bear out the correctness of the foregoing assertion. It seems an inevitable law of Nature that when the cultivation of any plant, fruit, or vegetable is suddenly taken up on a huge scale, that particular form of vegetation in a short time falls a prey to hosts of insect pests and diseases, even when the most approved methods of culture are pursued. Experience may teach us how to still further improve our methods, yet it seems impossible under some circumstances to successfully combat our enemies by relying on good culture alone. Take, for example, the fungoid diseases which play such havoc with Tomatoes. A splendid start is made early in the season, former errors are avoided, and unceasing attention given to the plants, yet with all the care, the watchfulness, the hard fighting, the dreaded enemy puts in an appearance just when prospects appear the brightest. Fight as we may then with old weapons, and on old lines, we can only win a doubtful victory. No amount of valour and tenacity will avail by attacking our foe in front; our reasoning powers must be used to outflank the enemy, to make an unexpected attack at a vulnerable point, and thus nip further development in the bud. In the gardener's war against Tomato diseases the general who directs the strategy is the pathologist, who by close study of parasitic fungi is able to tell us the exact time at which to combat the foe with the surest results, that time being before the fungus produces its myriads of spores, which spread disaster around. Now, by dressing the borders and spraying the plants with fungicides, we are able with ease and certainty to accomplish a task which has beaten some of the foremost cultivators when making a direct attack instead of a "turning movement" under the guidance of the scientist.

In other phases of their daily life gardeners throughout the length and breadth of the land have to constantly adapt their methods to altered circumstances, as changes are ever taking place in the requirements they have to supply, and that too in the face of reduced expenditure. The gardens must still be kept gay and trim, the wants of the mansion unfailingly supplied, while additional duties in connection with public functions are heaped upon them. When such matters are pressed to the front it is evident that success in all directions equal to that of former years cannot be achieved by following in the beaten track; new methods of management have to be thought out, the machine becomes more complicated, and needs a closer supervision of the guiding brain than in days of yore. Tasks which were formerly accomplished in an easy methodical manner have to be done by the aid of subtle manoeuvre, which brings the necessary force to a given point just at the required time. Such is work which needs concentration of thought and action, judgment, and wise discrimination, as well as the old qualities of quick execution, or tenacity of purpose.

Fortunate, too, were many gardeners of old who lived in times when the supply of capable men to fill responsible positions was not equal to the demand; changes could then be made without much misgiving as to the future. The man who contemplates such a change now must perforce exercise caution, sometimes even justifiable strategy, in order to improve, instead of retard, his prospects. Sound advice on this point at the present time is, Be satisfied with your present position till you see definite prospects of improving it.

Let us turn for a moment to the commerce of the world. What startling and carefully planned "turning movements" seem to have become necessary. The vast and rapidly increasing population of civilised countries find their very existence depends upon securing opportunities for expansion, and thus all forward and colonising movements are influenced to a great extent by the necessity for commercial advantages and developments, which things are as the breath of a living nation; but wherever justice and equality follow in the wake of expansion the world is the better. Turning to commerce as conducted at home, is it not a startling and amusing sign of the competition of the present time that free gifts have to be dangled as baits to secure customers? In the commerce of horticulture we have not

yet arrived at such a strait as this, but who can say how soon it may come? the thin end of the wedge is, I fancy, already inserted. This, however, is certain—viz., that the trade has to be conducted with a greater amount of "strategy" and with more gigantic "turning movements" than at any previous period.

We are indeed passing through stirring times, and it behoves us all sometimes to think calmly of matters connected with our calling; and our race, as each thinker who unearths a hidden truth, or awakens a slumbering sentiment, which will stir into activity the "Micawbers" of to-day—be they in the horticultural world, or the world at large—adds something, however small, to the credit of the craft he follows. The midnight hour has struck, the morn will soon be with us, when gardeners will sally forth to their daily task, to their endeavours to make the earth smile with beauty and plenty; and to millions throughout the empire at the first streak of dawn will come the stirring thought, "What news from the front?"—ONWARD.

PROPAGATING VINES FROM EYES.

IN many private gardens the propagation of Vine eyes is only carried out in a small way. Often a Vine or two is all that are needed, and while many will prefer purchasing from the nursery, others choose to grow their own, and some there are who have no alternative but to do so. It is no uncommon incident in an interchange of visits by gardeners to find a few young Vines occupying a corner here or there, without there being any apparent use or purpose for them, and if by chance passing notice is made to them an immediate offer is made of a portion of the stock, which outnumber their home requirements.

Except for the introduction of some new variety by inarching there are many gardens in which Vine propagation is quite uncalled for, because the houses are fully stocked with healthy rods. In mixed vineries, however, it sometimes happens that there are some which are not satisfactory in their growth and fruit bearing, and to move them from among others well rooted is not easy or desirable, because of the injury that would be inflicted to those remaining. Here, then, is a case where inarching of another variety may do good without an undue expenditure of labour or loss of time, and it is optional whether the Grape be a new or old variety, or whether it is home-grown or obtained from the nursery.

Whatever course is decided on it is necessary that immediate steps are taken, and in rooting one's own this must be anticipated earlier when pruning is done, and the laterals plunged in the ground outdoors until required. Shoots that are well ripened and free from pith ought to be chosen for the purpose, cutting these with a sharp knife in a slanting direction about an inch below the eye, and a shorter sloping cut above. Pots filled with suitable soil—loam broken fine, lime rubble, and some leaf mould—being ready, the eyes can be at once inserted. Before doing so, however, some silver sand should be so placed that in pressing the eye into the soil the sand forms a base for the cut portion to rest on; this is helpful to early rooting. For a few days they may stand in a newly started forcing house, but later they require bottom heat, either from a bed of fermenting materials or the usual propagating frame. Once growth has commenced it should be steadily maintained, and as there is seldom an equal state of growth in every bud a few extra eyes ought to be put in to allow of an ultimate selection of the best.

Care is necessary in watering that the soil is not kept too moist, as it soon sours, and the plants then make no progress. As soon as it is ascertained that they are rooting freely, a transfer to other pots and new soil makes a rapid change in the growing shoot, and from this period bottom heat can be dispensed with. A warm structure, however, is still requisite, and a light position where they get the full benefit of sunshine. When produced for the purpose of inarching on to older Vines this operation can be carried out while they are in a green state, the union is then more certain and quickly effected. The choice of suitable growing shoots or laterals at the base of the Vine will need to be made early in the season; with this provision, and sturdy, free-growing Vines, the trouble of uniting them is slight, and by the end of the season the young Vine would be firmly established, and can be severed below the point of union at pruning time. The pots should be regularly supplied with water as long as there is leaf activity, and the ligatures carefully loosened as the canes swell. —W. S.

CYPRIPEDIUM MRS. FRED HARDY.

C. MRS. FRED HARDY was exhibited by Messrs. F. Sander & Co., St. Albans, in the early part of 1895, when it was honoured by the Orchid Committee of the Royal Horticultural Society. It was obtained from a cross between *C. superbiens* and *C. bellatulum*, and traces of both parents are readily observable. The petals are very striking and of much substance, with purplish spots on an almost pure white ground. The lip is somewhat small, and is of a dull white flushed with rose colour, darkening towards the mouth. The dorsal sepal is white faintly tinged with green, and having rows of dark maroon spots.

LÆLIA HARPOPHYLLA.

A GOOD form of this plant flowering now is about as cheery and bright an object as can well be imagined, and though the individual flowers do not come up to *L. purpurata* and similar kinds for size, they are at least equally beautiful and useful. Slender growing and not particularly strong rooting, *L. harpophylla* does not need a large receptacle, but in a cool, intermediate temperature, with small pots or baskets, it thrives well. Severe drying in winter is not to be recommended, and care is needed to keep it clear of white scale.

DENDROBIUM SUBCLAUSUM.

Bright red *Dendrobiums* are not common, and on this account, *D. subclausum*, a rather small-flowered species, recently introduced by Messrs. Veitch & Sons, will be worth noting. Pushing a large number of smallish bulbs from a slender central one, it reminds one a little of *D. Falconeri*, but the resemblance ends with the habit, as the flowers are totally different, being small and tubular. Ample heat and a very moist atmosphere during the growing season suit it well, and the effect of a plant of it well flowered is very light and pretty.

EPIDENDRUMS.

The recent award of a first-class certificate to the hybrid *Epidendrum* figured on page 89 was probably a surprise to many. Not but that it richly deserved the honour, for it is a very beautiful plant, but the genus has long been under a cloud that as yet shows little signs of lifting, and it is to be hoped that this hybrid will be the forerunner of others. Respecting the genus as a whole it may be termed a New World congener of the Old World *Dendrobium*, and the similarity of the name is also to be noted.

Like *Dendrobium*, it contains a few plants that are little better than botanical curiosities, weeds of the great Orchid family, but it also contains some splendid garden plants. Take one of the parents of the hybrid referred to as an instance—viz., *E. Wallisi*. This is a very fine plant, and the only reason I can think of that it is not more grown, is that in the rush for new *Cattleyas* and *Lælio-Cattleyas*, *Odontogloss*, and *Cypripediums*, about all of which there is a great similarity, the more varied beauties of the *Epidendrums* have been overlooked.

Of quite a different class is the richly tinted *E. nemorale*, a plant well worth a place in all collections, and of course the orange and scarlet *E. vitellinum* is equally worthy. But this is not a neglected plant by any means; instead it is one of the most popular. *E. radicans*, again, gets a fair shade of attention, but not as much as it deserves.

Perhaps the most beautiful of all is *E. bicornutum*, with its white starry blossoms growing from the top of its pseudo-bulbs. The latter, hollow as a horn, have been found very difficult to keep up to size for any number of years, and though a few cases are on record of successful culture extending over a considerable period, the fact remains that it is a difficult species. An atmosphere well quickened by heat, always reeking with moisture, constantly changing, and never shaded, was what I was told years ago suited this plant.

After vainly trying to get it, I grew the plant in the lightest part of the East Indian house, and was fairly successful with it. It is an

Orchid that dislikes root disturbance, and the most lasting description of compost must on this account be allowed. Taken as a whole, there are few months in the year when a house devoted to *Epidendrums* was without flower, and to gather together and cultivate a representative collection would be very interesting.

COMPARETTIA FALCATA.

This is a very charming little Orchid, not often seen in creditable condition, for, like others of a similar habit, there is not much to come and go on, and the result of a severe check is to so paralyse the whole system of the plant that recovery is slow and doubtful. But newly imported pieces usually go on and flower for a year or two, and from these it is evident that the plant would become popular were it less fastidious. There are no doubt many places up and down the country where *C. falcata* has been grown and flowered for a considerable period, but they are few in comparison with the number of Orchid collections generally.

FIG. 33.—CYPRIPEDIUM MRS. FRED HARDY.

One such instance I know, and in this case the plants thrive well in a cool light fernery on a lattice stage over an open tank. Any receptacle that allows of perfect ventilation to the roots and does not hold a very large amount of compost will suit it well, and a very useful material is Tree Fern stem cut into short lengths. The flowers, purplish red in colour, are usually an inch or so across, borne about half a dozen together on pendant spikes. The plant is widely distributed in Guatemala, Cuba, and Ecuador, and possibly in other adjacent countries. It is an old species in gardens, having been figured in the "Botanical Register" in 1840.—H. R. R.

FRUIT STONES.—The stones of Peaches, Apricots, Nectarines, Plums, and Prunes, heretofore thrown away or used for fuel in California, are now articles of commerce, and realise from 8 dols. to 10 dols. a ton delivered in San Francisco. From the Apricot kernel French "nut candy" is made, displacing the Almond. Cinnamon, allspice, and nutmeg are adulterated with this same source, ground and highly prepared. Prussic acid and essence and oil of almonds are made from the Peach and Prune stones, and these flavours are used in a thousand different ways.

PRUNING MARÉCHAL NIEL.

REFERRING to the interesting article on Maréchal Niel by "H. S." on page 92 of our Journal, will the writer please say what became of the old shoots that were not pruned away but left to encourage the plants to make new growth? I suppose the "long clean rods" made were from the base and not from the old shoots left uncut; when were these old shoots removed or dealt with?—S. S.

MARÉCHAL NIEL.

I WAS interested in "H. S.'s" notes on this grand Rose in your issue for February 1st, as I have tried both plans of pruning. It seems to me we really want to take more consideration as to the main object when pruning Maréchal Niel. For example, if the house is devoted to that Rose alone, and the roof covered, I would certainly prune by cutting out weakly and old or partially worn-out wood; but when a number of other plants are to be grown, as is so frequently the case among amateurs, I believe in hard pruning as soon as the crop of flowers has been secured.

There seems to be no reason to assume that heat has any effect upon the colour of this beautiful yellow Rose. Under the same conditions, and even upon the same plant at the same time, I have frequently found great variations in colour. Nor have I noticed any permanent difference when upon any given stock. De la Grifferaie, Briar in all forms, various varieties of other Roses, such as Madame Berard and Gloire de Dijon, have all been used as stocks, without any appreciable fixture of the deep golden yellow that is so much more attractive than the paler forms.

POT ROSES.

These need considerable care and attention now, and if neglected the results cannot be satisfactory. Too much air or ventilation is more often than not the primary cause of check, flowerless growths, and mildew attacks. A steady and uniform temperature will bring on Roses much better and safer than a too rapid excitement. We get our crop of flowers earlier in this way. Hard forcing only exhausts the latent sap in the wood and roots before the latter can produce more, and the inevitable consequence is a severe check. After the roots are at work a rise of temperature will soon induce quick and unchecked growth. Insects are already troublesome, and will be most harmful unless we attack them at once. By no means use strong measures. There is no lack of good insecticides on the market, which must be used according to the advertised instructions.

A SELECT DOZEN FOR POTS.

Just at present cut Roses are a great help for indoor decoration, and are seldom more appreciated than during the time of Narcissus, Lily of the Valley, Roman Hyacinth, and other white flowers. The soft colours of the Teas and Noisettes, with their delicate perfumes, make them doubly welcome. But in order to have the best show of flower thus early in the season we must pay a little attention to the class of Rose grown. The following dozen cannot fail to please for pot work; and all force well, flower freely, are quite distinct, and open with freedom:—Niphetos, Perle des Jardins, Madame Lambard, G. Nabonnand, Isabella Sprunt, Catherine Mermet, Maman Cochet, Madame Falcot, Kaiserin Augusta Victoria, Papa Gontier, Gruss an Teplitz, and Sunrise.

PAUL NABONNAND.

A Rose that has come into our markets rather freely during this and last winter does not appear in many English catalogues. At the last annual meeting of the National Rose Society more than one member inquired its name, and some replied it was Red Safrano. One of our most prominent prizewinners among amateur growers was told the same, but he at once said it had no connection with Safrano. The proper name of this really charming Rose is Paul Nabonnand, one of the many grand decorative varieties sent out by Nabonnand (1878), and also one that has apparently been overlooked by most growers on this side of the Channel. Paul Nabonnand is a good grower, very free-blooming, carries the flowers boldly upon stiff and long stalks, lasts well, and is one of the best forcing Roses we have. Its colour is a very soft but quite clear rose, much deeper in the centre, and simply grand for cut work and in the bud stage.

MRS. ROBERT GARRETT.

Another Rose that growers must not miss is Mrs. Robert Garrett, a beautiful soft salmon pink form of Caroline Testout, and rather

better formed. It has been exceptionally good with me. There are several new Roses of last season that deserve mention, and I will endeavour to name a few of the best, giving a brief description, in an early issue.—PRACTICE.

CALADIUMS.

NOBLE foliage plants indeed are these, with such quaint markings and beautiful colouration of leafage, that when well grown they invariably command unstinted admiration. Yet notwithstanding all these good qualities, it is, I think, an undoubted fact that they are not so generally grown in gardens as they were twenty years ago. This is certainly not on account of the difficulty of their culture, as few plants are more easily grown, and many of the best varieties are specially suitable for decorative purposes. When arranged with other plants they add materially to the general effect on account of the distinctness of their leaves.

The miniature *C. argyrites* is well nigh indispensable for dotting in groups or furnishing the edges of jardinières and plant stands, and this silvery leaved Caladium is, I think, grown more largely than any other. Varieties of bolder growth are, however, to my mind quite as useful, as when placed in isolated vases or bowls they are particularly striking in appearance. For such purposes, however, they need to be well and sturdily grown, and also placed in an intermediate house for a few days, or they do not last well in dwelling rooms, but when properly treated they will, during summertime, remain in good condition in such positions as long as the majority of plants employed for decorative purposes, if we except such plants as Palms and Dracænas. Another point which should strongly recommend Caladiums to cultivators generally is that they do not take up valuable space in winter, and when such plants are grown they make room in the autumn for large stocks of those indispensable winter flowering plants, Poinsettias and Euphorbias.

The end of February or early in March is an excellent time to start a few tubers, following with the main batch a few weeks later. Shake away the old soil, and place each tuber in a small pot, using a light compost formed of turfy loam, peat, and leaf soil in equal proportions, with plenty of sharp sand added. If possible bottom heat should be given, and a night temperature ranging from 60° to 65°, with daily syringings, and the moist atmosphere maintained in stores generally. The tubers will soon start into growth, and when well rooted are ready for shifting into larger pots. Those from 5 to 7 inches in diameter are suitable sizes for plants intended for decorative purposes, but if large specimens are required, from six to eight tubers should be placed in a 10 or 12-inch pot. The soil for the final potting ought to be used in a rough state, so that the large quantities of water needed may pass freely through it, and to the ingredients already named a little dried cow manure, broken in pieces with the hand, or rubbed through a half-inch sieve, may be added. When using large pots fully one-third of their depth should be occupied by drainage, using rough potsherds for the lower layers, and finishing off with smaller ones, these to be covered with rough peat or fibrous loam.

After potting the plants should if possible be given a little bottom heat for a time; indeed, bottom heat is of great assistance in promoting clean, strong, healthy growths, quite up to the time that the plants are fully developed. Old houses are often well adapted for growing Caladiums, because in such lean-to structures there is often a central bed well furnished with pipes for supplying bottom heat. These beds are usually rather deep, having originally been used for Pine growing, and their surface is within 4 or 5 feet of the glass; here, then, is an ideal position for growing Caladiums. Plunge the pots about half their depth in cocoa-nut fibre, syringing two or three times daily during bright weather, and shade for a few hours; the plants will then make rapid growth, and in time develop highly coloured leaves. Heat and moisture are the great essentials to success throughout the growing season, but a dry hot atmosphere Caladiums detest, as it causes the leaves to go brown at the edges, and sometimes to flag badly. Very little air is needed even in summer time, with the exception of a week before the plants are required for exhibition or decorative purposes, but the moistening of floors and walls must be regularly attended to.

When rapid growth is being made, and the roots are active, copious supplies of water are needed; the soil ought never to be allowed to get quite dry, as the plants seem to revel in rough soil kept constantly moist, but when grown on an ordinary stage without

bottom heat more care is needed in watering. In early autumn when the foliage begins to turn yellow, water must be gradually withheld till the leaves die down completely, the pots can then be placed on their sides beneath the stage in a stove temperature. A few times during the winter the soil ought to be examined, and if very dry be

Dr. Lindley, Gaze de Paris, Mars, Mrs. Laing, Prince Albert Edward, Triomphe de l'Exposition, Regina Victoria, and Wighti. Some of the dwarf crimson forms are very beautiful, of which the illustration (fig. 34) is a typical example.

Those who intend to make a speciality of these attractive foliated

FIG. 34.—A GOOD TYPE OF CALADIUM.

watered, as if kept in a thoroughly parched state throughout the winter the tubers often decay in the centre.

The pretty argyrites should be grown in quantity, as it brightens the edges of a stage so well, and is constantly in demand for other decorative purposes. Other good varieties are Aida, Fermingi, Auguste Lemoine, Baron de Rothschild, bicolor splendens, Chantini, Chelsoni,

plants will do well to visit, during April or May, some well known nursery where they are largely grown. They can then secure plants which take their fancy in time to grow them into nice specimens the same season. It seems a pity that a class for Caladiums is not provided at a greater number of shows, and nurserymen might give an impetus to their culture by offering prizes for special varieties.—PLANTSMAN.

KINGSTON AND SURBITON CHRYSANTHEMUM SOCIETY.

THE annual general meeting of this Society was held at the Kingston Coffee Tavern on the evening of Monday, February 12th. There was an unusually large attendance of members. Mr. William Drewett presided.

The report showed that the Committee have closed the accounts for the year 1899 in a better condition than for a time seemed possible, though they regret that it has not been done without falling back on Rule 6 of the Society, which says: "The full amount of prizes offered will be paid if the funds admit; but should they prove insufficient they will be paid in proportion to the funds."

Having briefly stated the drawbacks under which the Committee have had to labour for two years, it is pleasing to be able to present a balance-sheet showing a sum in hand of £1 14s. 9d. To that has since been added two other sums got in, increasing the balance to £3 3s. 8d., and hopes are entertained of recovering a little more.

The Society now stands clear of all pecuniary obligations, though it had been hoped to realise sufficient to make up the prize money to the full amount. In these encouraging circumstances the Committee appeal for continued support from subscribers, and give the assurance that strenuous efforts will be put forth to make the twenty-fourth exhibition of the Kingston and Surbiton Chrysanthemum Society more attractive by providing additional classes for "small growers" and amateurs.

The Committee desire to acknowledge the liberality of Sir Whittaker and Lady Ellis, and thank the worthy Baronet for doing the Society the honour of being its President during the year he filled the office of High Sheriff of Surrey.

This report and balance-sheet was adopted without material discussion, and was regarded as particularly satisfactory. Mr. A. Dean remarked that the Society was under great obligation to Mr. Drewett, who had, in his capacity as Chairman of the Committee, been thus able to place before the members so excellent a financial statement. Sir J. Whittaker Ellis, Bart., High Sheriff of the county of Surrey, was unanimously elected to the position of President. The list of Vice-Presidents and Lady Patronesses, rather lengthy ones, was left to the Committee to revise and complete. Mr. A. W. Homersham was unanimously re-elected Treasurer, being also thanked for his services, and Mr. W. Hayward, florist, Fife Road, Kingston, was elected Secretary.

A tough contest then took place for the membership of Committee, twenty members having to be elected, twenty-three persons being proposed. The voting was by ballot, and it was found that Messrs. W. Drewett, W. E. Wells, A. Dean, Randall, Hawkes, Pitcher, Neave, Cusbon, Blencowe, Smart, Lane, Atkins, Dorsett, Hill-Jenkins, Watts, Bolton, McCormack, Gibbons, and Pead were elected. Of this number twelve were gardeners, and representative of a wide district. It was agreed to hold a meeting of the Committee on the 18th inst. A cordial vote of thanks to the Chairman closed the proceedings.

MADAME CARNOT AND OTHER SPORTS.

MANY growers will welcome the Crimson Carnot with open arms, but from the remarks of Mr. Wells we may infer that he is far from satisfied that he has the correct thing. Your correspondent is not the only grower to whom Mr. Perkins wrote to inquire as to the value of the "sport," and one asked for information as to whether it was a stem or root sport, to which request no reply has been received. How many have fancied that they had sports by a plant coming contrary to the colour expected, when it was simply a matter of cutting or label getting into the wrong pot. Mr. Wells says the bloom on the plant was similar to John Shrimpton, and attributes the short florets to the cramped pot room. Most growers' experience of a late and poorly grown bloom of Madame Carnot is that the florets come long and narrow and the bloom quite opposite in form to J. Shrimpton. Your correspondent further hopes that the buds in the small plant will come the same colour. Surely a plant rooted in May and giving a crimson bloom in December is not likely to revert to white again in February?

Anyhow it is a most extraordinary occurrence that the most beautiful white variety should favour us with two shades of yellow, then a pink, and now a crimson. It will be the first time, I believe, that a white has sported to a crimson. Whenever the "Crimson Carnot," pure and simple, is beyond dispute, it will be the finest acquisition of recent years.

Writing of sports, is it not remarkable how constitution and habit

of growth are frequently altered? With Madame Desgrange the yellow sports are later in bloom and better in foliage. Now we have a white sport which is whiter and larger than the parent. On the other hand how many times has Mrs. Ritson, the white sport of Vivian Morel, been found on the exhibition board? With most, if not all growers, it can only be got one-half the size of its parents. Then who can (or could) grow Mrs. Trafford equal to its parent, W. Tricker? and finally, who has seen the Crimson Pride of Madford (Mabel Kerslake and Pride of Stokell) to equal in size and form their parents? It is very plain that sports do vary considerably in habit and constitution as well as in the colour of blooms.—W. J. GODFREY.

THE QUEEN.

THE Queen is not a new variety, but was sent over from America in 1894, or, perhaps, one year earlier. It, however, received a certificate on November 17th, 1894, from the Floral Committee of the N.C.S., where it was staged by Mr. H. J. Jones. During that and two subsequent years I grew plants of it for the production of exhibition blooms, but being unsuitable for that purpose, and developing suitable traits in its character for late blossoms, it was relegated to that position, and has been grown thus ever since with success.—E. MOLYNEUX.

DECORATIVE CHRYSANTHEMUMS.

"W. S., Wilts," asks on page 98 for information respecting decorative varieties, and especially those suitable for January cutting, asserting that there are not many varieties that can be claimed to be January flowering under natural conditions. We must first form an idea what is "natural." I suppose a plant that is rooted in heat, grown in a pot, the growths stopped and tied to stakes, and the growths or buds in any way trimmed or restricted cannot be called natural growth. I take it "W. S." means late flowering without special treatment.

During the past season I caused to be grown nearly 4000 plants in over 100 varieties solely with the object of discovering which were best for decorative or market purposes, and I may add such experiment will not again be repeated—at least, upon such an extensive scale, for although the trial has been instructive and interesting it was far from remunerative.

There is, comparatively speaking, very little demand for decorative varieties, and those who grow them are not struck with the "Mum fever" to anything like the same degree as are growers of exhibition Japs. In spite of all that is being said as to the little encouragement given to Anemone-flowered, single-flowered, and other sections, it is the monster blooms of the Japanese section on the formal green boards which have promoted, and will continue to promote, the fancy for Chrysanthemums. And again, in spite of all that is being written about colour, form, and freshness of the blooms, size is the first consideration with all of our prominent judges. "W. S." in his mention of that superb variety, R. Hooper Pearson, hints at its being deficient in size for the boards. We are years behind the Americans in judging the merits of Chrysanthemums. With them colour stands first, but then the blooms must have stems sufficiently strong or stiff enough to hold the head up without ties or wires. With the Americans blooms are grown for decoration or to be admired for their beauty. With us to win prizes is the main object, and I again repeat size stands first. Such dull, colourless, or "muddy tinted" varieties as Mrs. W. H. Lees, Mrs. H. Payne, Australie, International, Lady E. Clarke, Madame C. de Terrail, and others would not be countenanced in America; but such varieties as R. H. Pearson, Mrs. Mease, Elma, Mrs. Coombes, H. J. Jones, and Miss Alice Byron are preferred.

But to return to our text, "Decorative Varieties," as understood by me. I believe I am correct in asserting that the Floral Committee of the N.C.S. has decided not to award a F.C.C. to a variety of this section. This, to a certain extent, is "throwing cold water" on the class. As to good varieties for late blooms, I would recommend, as whites, Christmas Favourite, Mdle. T. Panckoucke, Mrs. Peabody, Mrs. M. Simpson, and Madame A. D. Chatin; Madame P. Rivoire is fine for late December, but requires to be topped late and kept cool if required after Christmas. As a late yellow nothing equals H. W. Rieman. King of Plumes is somewhat earlier, but most useful for sprays. Captain Dellamy, a clear yellow, for late December is strongly recommended. In pinks nothing seems to surpass Madame Perrin, whilst Belle of Castlewood is a delicate flesh-coloured variety which comes in during January. Matthew Hodgson is a good brick red that can be brought in late. Master H. Tucker, as a chestnut-red colour for Christmas and early January, has no equal; the bloom is large, stem good, and it is an easy grower. Royal Standard is darker and very promising.

It must be understood that these are recommended for pot culture. For the planting-out and lifting system some are not suitable.—W. J. GODFREY.

Recent Weather in London.—One of the heaviest snow storms for many years visited the metropolis on Saturday evening. The fall commenced just after five o'clock and continued for about two and a half hours, during which time upwards of 4 inches came down. The night and Sunday were frosty, but on Monday there came a gradual thaw which was welcomed by many, notwithstanding the slush it created. On Tuesday it was dull and light snow fell at intervals, more freely at night, continuing on Wednesday with a steady thaw.

Weather in the North.—The frost that set in with the beginning of the month continues with increased severity, having ranged from 13° on the 5th to 22° on Sunday morning. Heavy snowfalls are reported from both north and south of the country, and the appearance on Monday with 19° of frost was quite unchanged.—B. D., *S. Perthshire*.

Gardening Appointments.—We learn that Mr. Henderson has resigned his appointment at Thoresby, after thirty-eight years' service, on an annuity which his late employer left him at his death. His foreman, Mr. William Robertson, succeeds him. Mr. J. Barson, for the past five years general foreman at Eastnor Castle, and previously at Osberton Hall, Notts, has been appointed head gardener to the Earl of Sandwich, Hinchbrook, Huntingdon. Mr. James MacMachan, late head gardener to H. B. St. George, Esq., of Brackernagh Lodge, County Galway, has been appointed to a similar position in the gardens of E. F. Baker, Esq., Tuxedo Park, New York, U.S.A.; and Mr. John J. Brian, late head gardener to Sir Edward Hudson Rinehan, Bart., Glanville Manor, Fermoy, has been appointed head gardener to Captain Rye, D.L., Ryecourt, Cork, in succession to Mr. S. McLean.

Fruit Tree Pruning.—It has always impressed me, since coming to years of discretion, that half the operators in the above process, if asked the best time to prune fruit trees, would name the winter. I am a strong advocate of summer pruning, or pinching, but where this is done it has to serve in many instances for both seasons, on the score that as the tree looks tidy and trim, other more important (?) work must receive attention. This reasoning is radically wrong, and should not be allowed a place in any gardener's mind. All the same, it is a fact that if anything has to be neglected in the routine of gardening it is the fruit trees. This cannot be denied, at least in a large district known to me. Whether trees were summer pruned or not they should be put in order now, as nothing looks so ungardenerlike as an ill-pruned tree, whether on a wall or in the open ground.—A. MIDLAND GARDENER.

The Season's Bloom.—It may be rather early yet to take stock of fruit bloom prospects. Certainly there is no lack of buds, Nature having done her part in furnishing those in abundance. Further, we have had rain in much greater plenty than fell last winter, and, so far, the outlook is promising. But one of the most agreeable features of the winter up to the present time at least, has been the entire absence of exceptionally warm days, such as we have often had at Christmas, and in January and February, and which warmth has so often forced bloom buds open weeks before they should under normal conditions be. We have now got into February, and nothing in connection with fruit production outdoors is forward, indeed all things are in a very restful condition. If we can find the same comparatively dormant condition existing when we get into March then we shall have good reason for hope. Early in April is quite soon enough for Peaches, Nectarines, and Apricots to bloom, and towards the end of the month for Pears, Plums, or other fruits on east or west walls, with early in May for Apples and Pears in the open. All the settings, if the bloom expands at the times named, have the advantage of greater warmth and light to assist fertilisation, and fecundation is much more rapidly secured. When bloom expands early it often does so before the fertile organs are fully matured, and then, if a spell of considerable cold follows, pollen grains are greatly injured. No weather conditions seem to be more productive of a good fruit crop than does a cold winter and a warm spring.—A. D.

Royal Meteorological Society.—At the ordinary meeting of the Society to be held at the Institution of Civil Engineers, Great George Street, Westminster, on Wednesday, the 21st inst., at 7.30 P.M., the following papers will be read:—"Report on the Phenological Observations for 1899," by Edward Mawley, F.R.Met.Soc., F.R.H.S. "Results of Percolation Experiments at Rothamsted, 1870-99," by Robert H. Scott, D.Sc., F.R.S.

Presentation to Mr. J. Barson.—Mr. J. Barson, who on his leaving Eastnor Castle, where he has been general foreman for the past five years, was on February 8th presented with a handsome silver tea and coffee service from the staff in the Castle Gardens. Mr. G. Mullins, the head gardener, made the presentation, and said Mr. Barson had the good wishes of all in his new undertaking. In addition to the above Mr. Barson was presented with a handsome marble clock from the members of the Eastnor Castle Cricket Club.

Renewing Fruit Trees.—Many blanks in gardens and orchards remain to be filled, and spring planting rightly done answers very well. Usually the best fruit catalogues give sound hints as to varieties most suitable for certain positions, but every fruit grower should give his closest attention to those best adapted to the soil and situation at his command. Never plant a tree in the previous one's position without using fresh soil. A good top spit of old meadow land, incorporated with road scrapings if too retentive, a little decayed manure, and mortar rubble or lime scraps, especially if for stone fruit, should prove a good medium for most fruit trees to thrive in. Take out the old soil 1 yard deep and wide, and if the situation is wet well drain with brickbats covered with turves. A stagnant subsoil is a common cause of the cracking in Pears as well as Apples. This may be remedied by healthy roots kept nearer the surface in sweet wholesome soil. Plant carefully and well, and good results will follow.—W. S. D.

Cunninghamia sinensis.—A native of the southern parts of China, this is one of the handsomest Conifers in cultivation, and at the same time one of the most difficult to deal with. In common with many other plants of this order, it has the habit of continuing to grow late in the autumn, and commencing again early in the spring, so that severe frosts cut these premature or unripened growths off, and cause the plants to assume a dwarfed, spreading condition, instead of making fine Araucaria-like specimens 40 to 50 feet high, as they do in their native habitat. Such being the case, it is only in warm, sheltered situations that it can be seen to the best advantage. It should be planted in a deep, rich, rather stiff but well drained soil, and must not be allowed to suffer from want of water at any time. The leaves, nearly 2 inches in length, are sickle-shaped with a twist at the base, coriaceous in texture, light green above, and marked beneath with two broad glaucous lines. The edges are serrated, a character which is far from being common among Conifers. It was first introduced to this country in 1804, but is not as yet either a common or a popular plant.—C.

Notes from Ireland.—The weather is severe, with snow and heavy night frosts. My footsteps left their imprint in the snow for several miles ere the seat of Lord Cloncurry at Lyons was reached. The time spent with Mr. Rigg, the gardener in chief, was most enjoyable. Carnations are a great speciality, and although the season is not the most propitious for tree Carnations, the house was very beautiful. The collection is a representative one. Mr. Rigg has raised a seedling which has a bright future before it. In an adjoining house Primulas and Cyclamens were strongly in evidence, also bulbous plants, and a specimen of *Daphne indica* diffused delightful fragrance. The experiments of Mr. A. Black of Carton, for the coming year, will be watched with interest, after his successful flowering of new hybrid Water Lilies in the open air. He is going to try and flower the *Victoria Regia* in the same pond, also to see if he can grow the *Papyrus antiquorum* outdoors. The Irish Gardeners' Association and Benevolent Society held its annual meeting on January the 25th. Mr. Cotter was President, and there was a fair attendance of members. The Secretary read the Committee's report for the year ending 31st December, 1899, which showed the Society was making slow but sure progress. The Chairman, in placing the report before the members for adoption, said he was glad to see the Society had made satisfactory progress and to know the monthly meetings were a success. Mr. McDonough seconded the motion. The officers for the ensuing year were then elected.—A. O'NEILL.

Timber in Victoria.—Mr. Perrin, the Victorian Conservator of Forests, reports that between the years 1888-89 and 1897-98, 615,603 valuable timber trees were planted by hand in permanent sites. In addition to these some 380,000 Blue Gums and Sugar Gums are thriving at Havelock, Majorca, and You Yangs. These, however, were sown broadcast and thinned out afterwards. The number of applications for surplus stock at the Macedon nursery continues to increase year by year. Nearly 50,000 were distributed from Macedon during 1898. The three most popular trees for the northern plains are the Sugar Gum, Pepper tree, and Locust tree, and to these may be added the Tallow Wood of New South Wales.

Bristol Gardeners' Association.—The fortnightly meeting of the Society was held at St. John's Parish Room, Redland, on Thursday, 8th inst., Mr. W. E. Groves presiding over a good attendance. Mr. Rogers of Staple Hill supplied the paper, which was on the subject of tuberous-rooted Begonias. Dealing with the culture of the plant in a very skilful manner, he said seeds should be sown in January in a temperature of 60° to 70°, pricked off as soon as possible, and kept potted as growth proceeded. The soil recommended for all stages was loam, leaf mould, and sand. For greenhouse purposes the plants should be kept in a light house, and as near the glass as possible, a damp atmosphere being the best for them. Mr. Rogers strongly urged the use of Begonias for bedding, and gave much valuable information regarding their culture for this purpose. A good discussion followed, and Mr. Rogers was accorded hearty thanks for his attendance. Prizes for an Orchid in bloom were awarded Messrs. Bannister and Newberry and a certificate of merit to Mr. Maddock for a well grown pair of Cyclamens.

Woolton Gardeners' Mutual Improvement Society.—A well attended meeting, comprising the best of the gardeners in the Woolton District, met together in the Mechanics' Institute on Thursday evening to hear a lecture by Mr. Duckett Cowan, a son of Mr. John Cowan, of The Nurseries, Gateacre, near Liverpool. The chair was occupied by Mr. R. Pinnington, of Roby. In introducing Mr. Duckett Cowan to give his lecture on "Reminiscences of My Travels in Collecting Orchids in South America," the Chairman complimented the Secretary and Committee on their varied programme for the session. Mr. Cowan at the outset briefly described his journey and the difficulty he had owing to his arriving at the time of the revolution, and continuing treated his audience to a most interesting dissertation, in which all the most interesting points were brought into conspicuous prominence. The lecture was a great success, being forcibly delivered and heartily appreciated. From the President's capital collection of Orchids came a splendid plant of the Woolton Wood variety of *Cypripedium Leeanaum* with twenty-four flowers, a credit to the owner and the gardener, Mr. Todd. A certificate was at once awarded. Votes of thanks to lecturer and Chairman closed the meeting.

Exeter Gardeners' Association.—At a recent meeting of the Devon and Exeter Gardeners' Association a paper on "Gardening as a Profession," was read by Mr. G. Camp, gardener to Mr. E. Byrom of Culver. The essayist, in dealing with the gardening profession of the present day, spoke of the many years of incessant study necessary to qualify the young gardener in the many branches of the art. He was continually under the influence of atmospheric conditions which physically affected him, and he was, moreover, constantly beset with obstacles that taxed his time and patience. The gardener's position, however, was one that required the careful consideration of all connected with it. The Gardeners' Royal Benevolent Institution was rendering valuable assistance to many infirm gardeners; but the funds of the Society were by no means adequate. He expressed surprise that so few gardeners subscribed to that Institution. Though the salaries were not high, each could contribute something. He expressed the idea that entertainments could be successfully carried out by the gardeners in aid of the funds of the Benevolent Society. In conclusion, Mr. Camp reviewed the great transformation which had taken place in horticulture during the past century, and also spoke of the researches that were continually going on in every part of the globe at the present day. Commenting on the improved standard of excellence of the produce of the British gardener, he urged that the time had come when greater efforts should be made on behalf of the profession, either independently or by strengthening the hands of the Gardeners' Benevolent Institution. Mr. Meyer occupied the chair. A discussion followed the reading of the paper, and a hearty vote of thanks was passed to the essayist.

Birmingham Gardeners' Association.—Mr. G. Gordon, V.M.H., delivered a lecture entitled "Garden Roses" on the 5th inst. before a good attendance of the members. Mr. W. B. Latham occupied the chair. After a comprehensive exposition on the cultivation especially of the Hybrid Perpetual Rose, including the pruning of climbing Roses, and for which a sparing use of the knife was advocated, a select list of several varieties of Roses suitable for growing near towns and smoky districts, adapted for cultivation by amateurs or small growers was given. Standards were not strongly recommended, unless for some of the climbing section budded upon tall standards, so that the long shoots might depend, and in time form very interesting fountain-like heads, covered with a profusion of bloom. An excellent discussion followed.

The Greatest Sugar Country.—The average yield of sugar to the acre of cane is greater in the Hawaiian Islands than in any other cane-growing country in the world, and its standing in this respect demands our attention. In "Harper's Weekly" there has appeared a most instructive review of the Hawaiian sugar industry, from which we learn that the yield varies a great deal; the average yield of Maui, for instance, is about 3½ tons of sugar to the acre. Hawaii's average is lowered by the smaller producing qualities of her leeward or dry side, but would not go lower than 4 tons; Kauai, from 4 to 5 tons; and Oahu, 6 to 7 tons. There are, of course, pieces of ground, even entire plantations, on each of these islands where the yield would greatly exceed the average of the island; one plantation of Oahu, for instance, yields 10 tons of sugar to the acre (it takes 7 to 8 tons of cane to produce a ton of sugar), and special yields of even 16 tons per acre have been obtained from given sections of the same Oahu plantation. The quality of these figures is the better appreciated by comparison with the yield of Louisiana. The average yield of Louisiana, according to the figures of Professor W. C. Stubbs, Director of the State Experiment Station, varies from 1 ton to 2½ tons of sugar per acre, the average being perhaps not over 1½ ton.

January Weather at Hodsock Priory, Worksop.—Mean temperature for the month, 38·8° + 2·5°; maximum in the screen, 52·5° on the 23rd; minimum in the screen, 26·5° on the 28th; minimum on the grass, 17° on the 21st; frosts in the shade, eight, on the grass twenty-six; sunshine, twenty-six hours, or 11 per cent. of the possible duration, difference from average, - 11. Rainfall, 2·93 inches, difference from average + 1·13; rain fell on twenty-one days, maximum fall 0·90 on the 6th. A mild and rather wet month, with very little frost. —J. MALLENDER.

January Weather at Dowlais.—Rainfall 6·34 inches, which fell on twenty-seven days. Greatest fall 1·30 inch on the 6th. Snow fell on the 26th and three following days, with the wind very cold. For the corresponding period last year the rainfall was 9·81 on twenty-two days. Temperatures: Mean maximum, 39·161°. Highest reading, 45° on the 17th, and down to 32° on the 31st; mean minimum, 30·387°. Lowest reading, 22° on the 4th and 5th; below freezing point on twenty-one nights. Highest reading in the sun, 63° on the 4th. Sunless days, eighteen. The prevailing direction of the wind was S.W. and W.—WM. MABBOTT.

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet.

The temperature has been very low, with cold north-easterly winds. About 4 inches of snow fell on the evening of the 10th inst.

SEED SALE—NON-GUARANTEED CLAUSE.

SPEAKING from memory, and not *ex cathedra*, I believe that the "non-warranty" clause only gives protection in cases of difference of quality or variety in one kind of seed, and that the dealer who sold "Turnip for Cauliflower" would get no more protection than he deserved from it. The clause referred to is an absolute necessity in the seed trade, and it would be almost impossible to do business without it. The imputation that it is used as a shelter for dishonest dealing is absolutely unfounded, as there is no more honest body existing than the seed trade as a whole, added to which a good reputation is the breath of life to its members, and the least suspicion of unfair dealing would ruin any seed-dealer in a few seasons. Without some protection every half-crown packet of seed sold would entail a risk of legal action and the loss of hundreds of pounds. Setting aside the remote chance of malicious false evidence, the risk of the accidental mixture or transposition of seeds by the purchaser or his assistants would be always present, the results of which are naturally, as a rule, put to the unfortunate seedsman's account.

But there is a much more important matter to be considered, which is the immense variation that results from good or bad cultivation, or the prevalence of exceptional heat or moisture during the whole or a part of the growing season. To give just one instance, which the case cited by "A. D." recalled to me. A large farmer near here asked my father to call and look at a field of Turnips grown from his seed. On arrival at the field he was shown a crop so long-necked and generally malformed that he promptly disowned them, and declared that such could not be the produce of a good stock of seed. "Well, I should have thought so too," said the farmer, "and should never have bought any more seed from you, only I happened to have a few pounds of seeds left over from last year, from which I grew one of the grandest crops ever seen. The two are side by side, and now no one can see any difference, both being equally bad." How far variation may go in this way would puzzle the best horticultural expert to define, and a question of this kind might as well be submitted to the test of tossing a coin as that of the average judge and jury.

If "A. D." would only look at the other side of the question he would easily see that a seedsman's life would "be not a happy one" if every packet of seed he sold the results of which did not equal his customer's expectations rendered him liable to damages and costs, whether the failure were owing to adverse seasons, the lack of knowledge, skill, or industry on the part of the purchaser, or any other cause.—CHAS. E. PEARSON, *Chilwell, Notts.*

APPLE HORMEAD PEARMAN.

ATTENTION is drawn to a highly serviceable but not generally grown Apple on page 124. It may, possibly, be also good for the orchard, but I have only grown and seen fruits equal to the one represented produced by cultivated garden trees. It is a remarkably fine fruit, but, then, Mr. Bunyard is a fine cultivator. It is above the ordinary size, and it is probably because the fruits are generally smaller that the variety is not commonly seen at exhibitions. If it were, trees of Hormead Pearmain would be more generally planted. The variety is a healthy and what may be described as a fruitful grower, spurring freely and naturally, and the fruits are when reasonably well grown quite large enough for use. The tree makes an excellent cordon and a model espalier.

The name Hormead's on the page quoted must be the result of a clerical error. When once visiting the late Dr. Hogg in Sussex, he stated that the name was wrongly given in most catalogues, as the Apple was not named after its raiser, but after the place with which it was associated, and hence the name Hormead Pearmain. I think the Doctor said it was a Sussex Apple. Perhaps Mr. Cheal may be acquainted with its origin. I have seen it bearing well in the Lowfield Nurseries, and I think it is a favourite Apple there.—POMOLOGIST.

PINCHING FRUIT TREES.

MR. GEORGE PICKER some time ago asked if any practical readers of the *Journal of Horticulture* could prove that by pinching or stopping the shoots of fruit trees large healthy fruit buds could be produced earlier than by trees that are not pinched. I, for one, say pinching will not produce buds earlier in such a case. If two Pear or Apple trees of the same variety were planted at the same time, one to be pinched, the other not, I venture to say it would be found that pinching to promote early fruiting is time thrown away. When pinching was first introduced did the teachers say pinch the trees into form, or did they say pinch to form fruit buds. Probably they said first form the tree so that it can be pinched afterwards if required.

Seeing that "our Journal" grows with the times, why not let fruit trees do the same for yielding full crops of high quality fruit? But will such be had in the best manner by discarding pinching after the trees are formed? I say it would not, but that bud formation is facilitated by pinching if this is done at the proper time. No exact time can be stated. The cultivator must determine that from the condition of the

tree. If done at the right time the natural course of sap will be diverted and take a circular course, which assists blossom buds to form that would not do so if pinching had not taken place.—H. MITCHELL.

BLOSSOM BUD FORMATION.

REFERRING to "A Lincolnshire Gardener's" article on page 87 of the *Journal*, I may say that no one of experience doubts that transplanting or judicious root-pruning throws fruit trees into bearing; but will your correspondent kindly say at what months of the year shoot pinching should be done, and the manner of doing it, to produce similar effects? There is much difference of opinion on this latter question, and the readers of our *Journal* would be interested in his observations on that phase of the matter.—S. S.

SWEET PEAS.

BETWEEN the suggested conference and the bi-centenary of the Sweet Pea these always welcome flowers are brought more than usually prominent at the present time. As regards a conference, the purpose of which is to classify them into some tangible shape. With respect to their colour sections, there would seem to be divergent opinions; some favour the idea, others do not see the necessity for such a course. This, however, is a matter that concerns the specialist more than the ordinary gardener. The large and increasing number of sorts makes a selection for general purposes an easy matter to make the all-sufficient number of packets, each of fifty or 100 seeds, as the case requires. Moreover, the inevitable "mixed" assortments offered meet many cases, and to such persons the suggestion of a conference is vague and uninteresting. Seedsman, even those who issue unpretentious catalogues, give due prominence to Sweet Peas, enumerating a list of names as well as the "mixed" packets for their patrons to choose between. The large flowering varieties, associated so closely with the name of Eckford, are those most growers will naturally select, and the time is no doubt not far distant when the ordinary strains will be entirely superseded, and find no place either in the seed store or catalogues.

The present month is one in which many make an attempt to sow a few for early gathering outdoors, but the presence of snow at the time of writing affords no prospect of this being done at present. All who have a frame in which a few pots may be sheltered can gain some time by sowing say half a dozen seeds in a 60-pot at once, and standing them therein. If a warmer position can be afforded them until they have made half an inch of growth flowers would be ready some days sooner, hardening them prior to planting finally in a cold frame for some time. The trouble of raising a few Sweet Peas thus is very little, and the gain more than compensates for it. Perhaps it is better to anticipate bad weather, and adopt the indoor sowing at an early period, say in January. There is then no disappointment from unfavourable weather, and once growth is set into action they can be kept steadily growing until the ground is in a suitable state and the weather propitious.

Soil for filling the pots is not a very important matter, nor is a quantity required in ordinary cases. The better, however, it is in quality, the stronger they would be in root growth; but any garden soil, enriched with decayed manure or leaf mould, will give good results. Crowding several seeds into a small space is a fatal mistake to make with Sweet Peas, as it is with every other plant produced by seed, whether in pots or the open ground. The value of thin sowing can be demonstrated by anyone who wishes to take the trouble to carry it out, and this both in its application to pots and the open border. The cost of the seed is of itself a justifying reason for adopting rational sowing, and the greater vigour, both of plant and flower, bring further reward. Like the edible Peas, these like rich soil, and the site changed as often as possible. No plant tires of the soil so soon as Peas, and for this reason gardeners adopt a successional course, sowing not oftener than every third year on the same ground. Where the means do not allow of this, the alternative is to trench the soil deeply, and thus bring to the surface some that has been for some time undisturbed, and incorporating at the same time short manure, preferably in a decayed state. By adopting a course of sowing a few pots of Sweet Peas in January or February there is no necessity for risking outdoor sowings until the ground is in a thoroughly pulverised state in March.

The custom by some specialists of offering collections of Sweet Peas varying in number, variety, and price is an excellent one, and is one that might well be more generally adopted. Those who have submitted them in this way find the patronage justify the action, and a selection of colours made by those who grow them largely is often more satisfactory to the buyer than that made individually.—W. S.

CANADIAN V. AMERICAN APPLES.—It is reported that the shipments during January of Canadian Apples, which are entering into serious competition with American fruit in the London market, were particularly heavy, in one day 7524 barrels, containing 22,572 bushels, having been unloaded. A fine variety of Newtown Pippins, hitherto exclusively obtained from American orchards, was among the importation. The culture of this variety in Canada promises more extensive shipments in the near future.

GARDENS AND GARDEN MANAGEMENT.

CHINA has probably been possessed of gardens in a general sense longer than any other country, except those recorded in the oldest and best book in the world. So far as I can learn no other country takes more interest in the culture of small plots of land, which may be called gardens, than China to-day. Greece and Rome paid some attention to the subject when in the heyday of their prosperity, but it was confined more to the large towns and cities than to the country districts.

Coming to our own country, we have to admit that gardens, as we understand them, are of comparatively modern creation. Climatic causes probably had much to do with this, though no doubt the cultivation of small plots of land was more general in the midseason of our civilisation than is the case now—in making this assertion I mean *pro rata* to the population. Various causes have brought about the great development of gardens in our time. I would fain hope that one of the greatest of these is the increased love of and interest in the purer pleasures of life, which must result from the work and reaping the produce of a well tilled and dressed garden, whether it be a large or a small one.

The extension of commerce caused by steam has no doubt added to our national wealth, whilst at the same time there has been a more equal distribution of it. Hence much larger numbers of the population are enabled to enjoy the pleasures produced by gardens than before. I am one of those practical enthusiasts who think that we are a long way from being at the end of our efforts in this respect—I allude to public and private gardens of all sorts and sizes, such as allotment gardens, botanic gardens, village gardens or playgrounds, Rose gardens, perennial gardens, alpine gardens, fruit gardens, school gardens, window gardens, and other forms. Of course, once we admit a covering of glass we may go on much further.

I must not now enter into the question of exhibitions of garden produce, the subject being too large. Suffice it to say that they are a nineteenth century creation, and so far as my experience goes have done much good on the whole, in increasing the interest in and the pleasures to be derived from gardens.

We now come to the management of gardens. For this, practice is obviously the first essential. Where should this practice be acquired? I would reply in a moderate-sized, well-managed garden, where good average results are obtained. On this subject I would say to young men—Do not be too anxious for a time to get under a glass roof. In these days of multiplication of glass houses, and the consequent interest in what is grown therein, there is danger of outdoor practice being looked down upon. Most gardeners who have passed the meridian of life will bear me out when I say that the base of all sound gardening is to be well grounded in outdoor work. A period of not less than three years is essential for this purpose. Apart from the necessary but somewhat limited demand for specialists, more men fail in outdoor than indoor gardening. By no means do I wish to speak lightly of what may be fitly termed the higher duties of a skilled gardener—viz., under glass culture. I only wish to show that in my experience more young men fail in managing the outside than the indoor department. I know of a garden owner who, when selecting a new garden manager, said, "I want a man who will give us a regular supply of the best vegetables. My place smells of Pine Apples, but we have not a fresh young Cabbage fit for the table."

Having become expert in the use of a spade and all other garden implements, the most important help for a young man is a well-kept memorandum book of times of sowing and planting and other necessary operations of outdoor crops. It is a good plan to write these in the left hand page, and leave the right hand one blank for remarks thereon. Attend to the smaller details of all outdoor work as closely as to the potting of a 20-guinea Orchid or other valuable plant. When changing situations try to get into one where the general culture is on somewhat different lines from the one you are leaving. Use a portion of your leisure time in reading and mastering good books and papers bearing upon the vocation you have chosen. As time goes on extend this reading and writing to other books. I do not say young men should not have recreation, far from it, I only wish to infer there is a time for all things.

After, say, ten years or upwards of such experience as I have hinted at, the time will come to look out for a garden to manage. The young man's first charge in this respect is a very important epoch in his life. Careful bearings should be taken. Besides the eyes of those who employ you those of your confrères will be more or less upon you. Pay strict attention to the wishes and instructions of the former; remember that, in the main, it is their time and means you are using. Do not be afraid of unthinking, if not ignorant, people classing you as merely a servant. To my mind the motto, "I serve," is a noble one, and the College of Heralds has not a better one inscribed on its records. Always be loyal to those who employ you. If a man is found faithful in small matters it may be the passport to a better

position; if not so, you have the consolation of knowing that you have tried to do your duty to the best of your ability.

When circumstances prevent this loyal service, seek the first opportunity of securing another situation; but have good grounds for your action. Of course there are unprincipled and unreasonable employers as well as servants of that sort. As a rule the former do not keep efficient gardeners very long, nor the latter succeed in life. Ascertain the likes and dislikes of those who employ you, and try to meet them. Aim at having all departments of the garden in as good general condition as the means at hand will allow; do not get shipwrecked at the outset in wanting to exhibit the produce grown under your management, if your employer objects. Most of them will grant this privilege in due time, if they find the general work well done. I once heard an employer remark "that the best exhibition table for his garden was his dinner table, drawing rooms, and garden generally." At the present day the majority of employers take a reasonable and liberal view of exhibiting.

Avoid trying to prove to your employer the incompetence of your predecessor. To me this is a blot on the fair fame of a body of men, who, in the main, sympathise with their fellow workers in our ancient craft. If things are in a neglected condition all the better for the new comer to show his skill and management. Visit other gardens when opportunity occurs. Few observant men can go into gardens without learning something either to imitate or avoid. In your dealings with those under your management try and secure their respect. This is best done by fair and consistent treatment. Do not always act as if the garden you are managing was especially made for your own pleasure. Of course, as manager, you are responsible for results, and must have orders obeyed.

Managers of most large gardens have more responsible positions than they used to have. Much more is expected than formerly, and too frequently the means to acquire these increased wants are more or less curtailed, hence the necessity of garden managers keeping their minds open to the best ideas and methods of production. A chief who has a loyal staff can make things meet far better than with a disloyal one. Do not neglect to take a personal interest in the general welfare of those employed under you. Try to be courteous and civil to all, and give help and encouragement when you can.

In conclusion I would say, Try to obtain as much produce and advantage from the means at hand as is possible, and speaking generally, you will be rewarded with a comfortable home, a clear conscience, and the respect of those who employ you.—(*A Paper read by Mr. H. J. CLAYTON, Grimston, at the Hesse Gardeners' Mutual Improvement Society.*)

RHODODENDRONS IN THE WOODLAND.

If the task were put before me to pick out the most indispensable shrub in the garden I should have no hesitation in naming the Rhododendron. When in full bloom in the early summer it is unsurpassed, and after the flowers have gone the habit of the plant and the bright green of its foliage make it a suitable specimen for any position. The Rhododendron, like other shrubs, has its likes and dislikes, though it is by no means fastidious. It delights in a light sandy compost well supplied with humus, and it shows a distaste for very heavy land and soil in which lime prevails. Thus we have it that in some places Rhododendrons grow so freely and increase so rapidly that they are almost weeds, while in others, in spite of made beds, there is difficulty in getting them to thrive. Fortunate, then, is the landscape gardener who pursues his occupation where Rhododendrons do well.

The garden culture of this useful shrub is an old theme, so I will extend my observations beyond the precincts of the garden to the woodland. In the first place my ideal pleasure ground is not that which surrounds so many English mansions, standing in the middle of parks, and having a forbidding fence encircling the domain. The happiest idea of a garden is seen in instances where the pleasure grounds blend naturally into the woodland without any definite boundary line, so that one really becomes part of the other. What a relief it is after the garden to find yourself almost unconsciously in the wild luxuriance of the woodland, about whose grass walks there is a softness and springiness that encourages one to proceed. A garden that ends abruptly lacks a great charm compared with that which loses itself gradually in woodland or wilderness.

The woodland, like the garden, may be well furnished, or it may be bare and uninteresting. Some woods can never be the latter, because Nature does the furnishing. She provides the Aconites and Bluebells, the Forget-me-nots and Periwinkles, and clothes the slopes and dells with Bracken and other Ferns, which have always a touch of beauty, whether it be in the bright emerald of early growth, the darker green of matured life, the yellow and golden brown of decay,

or the dead rustle of winter. There is no need to do much in such a woodland as this. A flowering shrub here, or a coloured foliage tree there, to lend variety, but any more elaborate attempts at furnishing detract from rather than add to the appearance. But Nature is not equally lavish with her gifts, and I have walked out of gardens into neighbouring woodlands where the change has been anything but cheering. Beneath the trees there is nothing more pleasing to hide the bareness of the ground than clumps of luxuriant Nettles; dead trees and broken branches give the place an uncared for look, and you search in vain for that fulness of vegetation which is usually connected with woodlands.

Obviously there is something wanting in such a spot, and what shrub more suitable for supplying the need than the Rhododendron? You may keep the choice hybrids for more conspicuous places within the limits of the garden, as the old-fashioned Rhododendron ponticum is the shrub for furnishing wood and wilderness, for which purpose

old stems, and wait till growth again commences; but if there is any objection to the bareness in the meantime, it may be obviated by starting at one side of the clump, thinning out the majority of the branches and pegging the others down, by which means the bushes instead of being done away with are simply lowered. For planting in game preserves and exposed positions, nothing is more suitable than *R. ponticum*. Rabbits will strip all the bark off young Laurels, but they never interfere with Rhododendrons, nor do the plants succumb to frost in the same way as other shrubs.

There is another position for which Rhododendrons are invaluable, and that is for the margins of woods and plantations. When a carriage drive runs through a woodland it is desirable to furnish the sides with shrubs, particularly if the plantations are of Firs which permit no undergrowth. For this purpose the common Rhododendron is invaluable, as it forms a natural belt. I know of nothing more pleasing than a long winding carriage drive with a broad margin

FIG. 35.—RHODODENDRONS AT SUNNINGDALE PARK.

nothing is more accommodating. If the soil is of light character and suits them they flourish and increase rapidly. They need little attention, and the leaves which fall from the deciduous trees provide a natural manure for the Rhododendrons beneath, as they root freely in the decayed foliage. One of the greatest mistakes with timber trees is that of growing them too thickly. How often does one see breadths of fine timber entirely spoiled by being so crowded together that it is quite impossible for any specimen to reach its proper dimensions? Where such is the case it would be beneficial in many instances if the trees were thinned, and the spaces between were planted with clumps of Rhododendron ponticum. There are places where the shrub is perfectly at home, and in such instances there is no difficulty in obtaining any number of seedlings for woodland planting.

Over-luxuriance is very often a fault of the common Rhododendron, and I have had to deal with immense clumps which were at one time effective, but had grown out of bounds and become nothing more than impenetrable thickets. In such cases a drastic measure is to boldly cut them down to the ground, plant seedlings in between the

of turf on each side, then a belt of Rhododendrons, with a background of tall trees. In the early part of June when the Rhododendrons are in full bloom, the effect is charming, and is greatly enhanced if variety is thought of by planting here and there a yellow Laburnum, a Gueldres Rose, and scarlet Thorn.

No one can have a taste for natural gardening without also being imbued with a weakness for the woodland—not the impenetrable thicket of crowded forest trees, which wrongly bears that name, but the natural picturesque woodland, where giants of the forest tower up, where the ground beneath instead of being bare and monotonous, is a wealth of undergrowth in which the common but indispensable Rhododendron ponticum finds a place.—G. H. H.

[Though the photograph reproduced in fig. 35 does not actually illustrate Rhododendron ponticum in the woodland as so ably advocated by our correspondent, it shows how these magnificent plants may be employed in the adornment of pleasure gardens in the immediate vicinity of mansions. The photograph was taken in the grounds of Sunningdale Park, and is reproduced by the kindness of Mr. F. J. Thorne, Major Joicey's able gardener.]

ONIONS.

In the sowing operations connected with the kitchen garden the Onion crop is one of the first to claim attention, inasmuch as Onions sown early have a better chance of attaining to some size and strength before the Onion fly commences to attack them. Another reason for early sowing is the longer season of growth which the crop can have, and thus practically insure a larger size in the bulbs than from later sown seeds. Those, however, who grow for exhibition do not, as a rule, depend on outdoor sowings, but provide themselves with good strong plants from January sowings in boxes in a cool house. When sown thinly in boxes and judiciously managed the young plants are of sufficient size and strength for planting out in April at the required distance apart for forming large bulbs. They soon become established, when the cultural operations of hoeing and feeding may be commenced and continued. Even by sowing in February in boxes earlier and stronger plants may be secured, which when planted out will rapidly grow beyond the attacks of the Onion fly, so for this reason the extra trouble experienced in the early stages is amply repaid by obtaining a more successful crop.

FEEDING.

The majority of growers who cultivate Onions for general use adopt outdoor sowing. Onions require a deep, rich, well-worked soil and an open sunny position. The ground should be freely enriched, such strong manures as fowl, pig, and night soil being best applied in autumn to ground intended for Onions; indeed all natural manures, including cow, horse, or general farmyard, are best worked into the soil some time previous to sowing, turning the soil well at the same time. Artificial manures are appreciated by Onions; nitrate of soda, kainit, and superphosphate may be applied at the rate of half a pound each about ten days before sowing to a square rod of ground, and a similar quantity when the young plants are 3 inches high.

LIQUID MANURES.

Nitrate of soda dissolved in water, but not in larger quantity than a quarter ounce to a gallon, acts quickly on the young seedlings. This stimulant must not be used too freely, but it may be varied by an application of guano 1 oz. to the gallon. Liquid manure made from strong animal manures is beneficial. A quarter of a peck to half a peck of fowl manure may be dissolved in 30 gallons of water, and be given frequently during active growth. Soot water is another good stimulant; this is made by tying a quarter peck of soot in a bag and immersing it in 30 gallons of water. Apply this alternately with other manures. Stimulants are only specially necessary when the largest sized bulbs are sought for, but good ordinary Onions of fair size and reliable keeping qualities may be grown on ground well worked and enriched.

SEED SOWING.

Soil prepared for Onions in autumn may be further forked over prior to sowing, and it is good practice to apply a dressing of wood ashes and soot, working these well into the surface, breaking down and pulverising the lumpy portions. After this tread the surface firmly, very light ground might be advantageously rolled; but all these operations must be carried out in dry weather, therefore it is best to choose the first opportunity in February for doing this. When ready for sowing rake the surface fine and level. The rows may be 1 foot apart, and the drills can be formed by pressing the back of an iron rake into the soil a quarter of an inch deep, having a garden line laid for guidance. Scatter the seeds thinly along the drills, and cover by drawing soil over them from the outside, pressing down firmly.

HOEING AND THINNING.

Further attention will not be necessary until the seedlings are well through the soil, when a light Dutch hoeing will be beneficial. Afterwards weeds must be pulled from among the plants and a preliminary thinning given. This is the time to stimulate growth by the application of artificial manure dressings or liquid manure, and hoe between the plants frequently, for this keeps down weeds, encourages growth, and prevents evaporation of moisture from the soil. Thin out the plants to the final distance apart as soon as practicable.

PLANTS FROM BOXES.

Onions sown in boxes must be protected from the weather until they are hardy enough and strong, which they will be by the month of April if gradually inured by cool frame treatment. It is desirable to give the planted out Onions exceptionally good soil, which may be prepared now by trenching and liberal manuring. When the time arrives for planting out draw shallow drills 12 inches apart, and place the Onions 6 inches asunder. Make the holes so that the roots can be placed straight downwards and not be curled up or twisted. Hoe the ground frequently afterwards to promote growth. The soil, if light, may be made firm previous to planting. When established afford the plants a light dressing of nitrate of soda, kainit, and superphosphate, half a pound each to a square rod of ground, and work it in with the Dutch hoe. Light dressings of pure soot are always beneficial to Onions, fertilising the ground and tending to keep away the fly.—E. BARROW.

ROYAL HORTICULTURAL SOCIETY.

ANNUAL GENERAL MEETING.

THE very unpropitious weather that has prevailed in the metropolis during the past few days had some effect on the number of persons attending the annual general meeting of the Royal Horticultural Society in the Lindley Library on Tuesday afternoon. Sir Trevor Lawrence, Bart., V.H.M., occupied the chair, and was supported by several members of the Council, while in front of the table were to be seen a very representative gathering of both amateur and professional horticulturists. Such preliminary business as the reading of the minutes of the previous annual meeting was quickly disposed of, and a considerable number of new Fellows were elected. The report and balance-sheet given hereunder, having been previously distributed, were taken as read.

REPORT OF THE COUNCIL FOR THE YEAR 1899-1900.

The year 1899-1900 has been one of continued prosperity for the Society.

A large sum of money has been spent on the Lindley Library in recent years, and the Council have now had the books enclosed in glass-fronted cases for the double purpose of preservation and cleanliness. This has greatly improved the appearance of the library.

A catalogue has been published at the price of 2s. 6d. in the hope that many Fellows would purchase it, not only to inform themselves what books the library contains, but also because it forms in itself a reference list to the bibliography of gardening. It would be gratifying if Fellows would also take note of books still wanting to the library, with a view to presenting them.

During the past year valuable books have been presented by the Director of the Royal Gardens at Kew, Dr. Maxwell Masters, F.R.S., Miss M. J. King, the Rev. Professor Henslow, V.M.H., Monsieur Correvo, Monsieur Bois, and others, to all of whom the best thanks of the Society are due. A full list will be published on April 1st in the Society's "Journal," vol. xxiii., part 3.

A corrected list of the awards made by the Society to plants, flowers, fruits and vegetables to the end of 1899 is being prepared, and will be issued during the coming year.

Application is frequently made to the Society by Fellows desiring to have special advice respecting their gardens. The Council have therefore resolved to add a right to this to the privileges of Fellowship and to send a competent inspector to report and advise at the following charges—viz., a fee of £2 2s. for one day (or £3 3s. for two days, when necessary), together with all out-of-pocket expenses. No inspection may take up more than two days.

Under the head of ordinary expenditure at Chiswick £1810 has been spent on the general work and maintenance of the gardens. The receipts by sale of surplus produce amount to £330, making the nett ordinary cost of the gardens £1480.

CHISWICK GARDENS.

The Council wish to call attention to the good work being done at Chiswick under Mr. Wright's superintendence not only in the garden but among the students. During the last two years, for example—of our Chiswick students, one has taken a First Class in Honours in Science and Art, one a First in Advanced Botany, two a First in Elementary Botany at South Kensington; one has been appointed curator of the Botanic Gardens at Antigua; seven have taken a First Class in the R.H.S. Examination in Horticulture; two have set up in business for themselves; four have obtained positions at the Royal Gardens, Kew; one at Kensington Gardens; two at Messrs. Veitch's; one at Messrs. Low's; three in other large nurseries; and one is editor, and another is on the editorial staff, of a garden paper. Mr. Wright reports to the Council:—"The demand for energetic trustworthy young men from Chiswick is rapidly increasing; there is no difficulty in placing such in good situations, our supply being unequal to the demand, but they *must all be workers*."

THE COMMITTEES.

At Westminster twenty-one Fruit and Floral meetings have been held in the Drill Hall, James Street, Victoria Street, besides the larger shows in the Temple Gardens on May 31st, June 1st and 2nd, and at the Crystal Palace on September 28th, 29th, and 30th. An International Conference on Hybridisation was held at Chiswick and Westminster Town Hall on July 11th and 12th. Lectures and demonstrations have been delivered at nineteen of the meetings.

The number of awards granted by the Council, on the recommendation of the various Committees, is as under:—Gold Flora medal, 1; R.H.S. gold medal, 22; silver cup, 24; Hogg Memorial medal, 1; silver-gilt Flora, 28; silver-gilt Knightian, 23; silver-gilt Banksian, 34; silver Flora, 97; silver Knightian, 21; silver Banksian, 170; bronze Flora, 20; bronze Knightian, 3; bronze Banksian, 44; first-class certificate, 65; award of merit, 291; botanical certificate, 16; cultural commendation, 42; highly commended, 8; commended, 1; total, 931. In addition to the above, 1 silver-gilt Flora has been awarded to Mr. H. H. Eaton for having passed first in the Society's examination; and 94 bronze Banksian medals have also been granted to cottagers' societies.

The Council desire to draw the attention of Fellows of the Society to the more extended use which the Scientific Committee might be to them if they availed themselves more freely of their privileges in

submitting instances of diseases of, or injuries to plants, caused by insects or otherwise. The Scientific Committee is composed of gentlemen qualified to give the best advice on all such subjects, either in respect to the prevention or cure of disease. The Committee is also glad to receive specimens of any subjects of horticultural or botanical interest.

SPECIAL EXHIBITIONS.

The Society's great show held in May (by the continued kindness of the Treasurer and Benchers) in the Inner Temple Gardens, was as successful as ever, and it is a matter of satisfaction to the Council to find that this meeting is now universally acknowledged to be the leading horticultural exhibition of this country. The best thanks of the Society are due to all who kindly brought their plants for exhibition, or otherwise contributed to the success of this show.

The International Conference on Hybridisation held at Chiswick and at Westminster Town Hall on July 11th and 12th was considered both by our home and also by our foreign guests to be an unqualified success, not only from the value of the papers read and communicated but also from the pleasant opportunity it afforded for the meeting of horticulturists from all parts of the world. The report of the Conference has been unavoidably delayed. It will form a distinct and very valuable volume of the Society's Journal.

The exhibition of British grown fruit held by the Society at the Crystal Palace on September 28th, 29th, and 30th was, considering the very unfavourable season, most satisfactory. Full particulars will be found in vol. xxiii., part 3 of the Journal, which will be issued in the course of a few weeks.

As an object-lesson in British fruit cultivation this annual show stands unrivalled, and is of national importance. Those who have visited it from year to year cannot fail to have been impressed by the wonderful advance which has been made in the quality of the hardy fruits exhibited. And as the importance of fruit growing in this country cannot well be over-estimated the Council invite Fellows and their friends to support them in their efforts to maintain and improve this Exhibition by visiting it, and by subscribing to its funds. For it cannot be too widely known that the continuance of the Show is absolutely dependant on at least £100 being raised by subscription each year towards the prize fund. The Show involves the Society in a very large expenditure without the possibility of any financial return. The Council have therefore established the rule that they will not continue it unless sufficient interest in it is taken by Fellows and their friends to provide £100 towards the prize fund. And this will in the coming year 1900, be even more important than heretofore, as the Directors of the Palace have signified to the Council that they feel compelled to decrease their contribution by £50. A glance at the list of subscribers will show how small has been the interest taken by the bulk of the Fellows. The Council would point out that this is not a local show with a few large prizes, but that a multitude of small prizes have been arranged in order to secure the best fruits in each section; special prizes have been allotted to market growers; and counties have been grouped in such a way that growers should not have to compete with exhibitors from localities more favoured by climatic conditions. These points will be still further extended should sufficient financial support be forthcoming. Subscriptions should be sent at once to the Secretary, 117, Victoria Street, Westminster, and if the list prove satisfactory the schedule will be issued in April, and the Show held on September 27th, 28th, and 29th, 1900. The list of subscribers for 1899 will be published in part 3 of vol. xxiii., of the Society's Journal.

An invitation was received and accepted for sending a deputation to visit a Show of Daffodils and other early spring flowers and produce, held at Truro on the 21st and 22nd of March, 1899. The Council desire to express their best thanks for the great courtesy and hospitality with which their deputation was received in Cornwall.

The Journal of the Society has been continued so as to enable Fellows at a distance to enter more fully into, and reap the benefits of the study and work of those actively engaged at head-quarters. Vol. xxii., part 4, and parts 1 and 2 of vol. xxiii., were issued during the year; vol. xxiii., part 3, will be ready on April 1st, and vol. xxiv., on the Hybrid Conference, as quickly as possible.

EXAMINATIONS.

An examination in the principles and practice of horticulture was held on April 11th, concurrently in different parts of the United Kingdom, a centre being established wherever a magistrate, clergyman, schoolmaster, or other responsible person accustomed to examinations would consent to act on the Society's behalf, in accordance with the rules laid down for its conduct. No limit as to the age, position, or previous training of the candidates was imposed. 165 candidates presented themselves for examination. The names and addresses of those who succeeded in satisfying the examiners, together with the number of marks assigned to each, will be found in the Society's Journal, vol. xxiii., page 64.

It is proposed to hold a similar examination in 1900, on Wednesday, April 25th. Candidates wishing to sit for the examination should make application during February to the Secretary, R.H.S. office, 117, Victoria Street, Westminster.

The thanks of the Society are due to all the members of the standing Committees—viz., the Scientific, the Fruit and Vegetable, the

Floral, the Orchid, and the Narcissus Committees, for the kind and patient attention which they have severally given to their departments.

The thanks of the Society are also due to all those who, either at home or abroad, have so kindly presented plants or seeds to the Gardens. A list of the donors has been prepared, and will be found in the Society's Journal, vol. xxiii., part 3, which will be issued on April 1st.

The Council wish to express, in their own name and in that of the Fellows of the Society, their great indebtedness to all who have so kindly contributed, either by the exhibition of plants, fruits, flowers, or vegetables, or by the reading of papers, to the success of the fortnightly meetings in the Drill Hall. They are glad to find by the increased and increasing number of visitors that the Society's fortnightly meetings are becoming fully appreciated by the Fellows and public in general.

A desire having been expressed that the so-called fortnightly meetings should be actually fortnightly throughout the whole year, it will be found by referring to the Book of Arrangements, 1900, that the Council have acceded to this request as far as it was possible to do so having regard to such obstacles to absolute regularity as the Temple and Crystal Palace Shows, and the occurrence of Bank Holidays.

Besides the lectures, delivered at various meetings, the Rev. Professor Henslow, V.M.H., has most kindly given several floral demonstrations, short accounts of which have appeared in the Journal.

A very courteous proposal has been received from the Richmond Horticultural Society, inviting the Council, with the Fruit, Floral, and Orchid Committees, to sit at Richmond on the occasion of the local Society's show in the Old Deer Park on Wednesday, June the 29th. This invitation has been cordially accepted, and the Committees will sit, and plants, &c., will be brought before them for certificate, exactly as if they were sitting at Westminster. Directions will be found in the Book of Arrangements, 1900.

THE NEW CHARTER.

Ever since the great revival of the Society in 1887 questions have from time to time arisen as to the legality of certain of the bye-laws. It has been urged that this or that bye-law was *ultra vires* because it was apparently in conflict with the Charter. And when recourse was had to the two Charters under which the Society is incorporated, the later (and therefore presumably the ruling) Charter was found to be so encumbered with matters relating solely to the South Kensington lease from the Commissioners of the 1851 Exhibition (which matters ceased in 1887 to have any further connection with the Society), that it seemed well-nigh impossible to separate the small residuum of the Charter that was still applicable to the Society's altered position, from the mass of enactments which had become obsolete and irrelevant.

There appeared to be only two alternatives, either to abide by the existing bye-laws, or to petition her Majesty to grant a new Charter. The expense involved in the latter course has hitherto been an obstacle, but at the beginning of the present year, 1899, the conditions of the Society's finances appeared to the Council to be such as to warrant a petition being made to her Majesty for a new Charter, and a considerable part of the year has been employed in drawing it up. The petition to her Majesty and a draft of the new Charter were submitted to a general meeting of the Society held on June 21st, 1899, and were unanimously adopted and ordered to be sealed with the Society's seal and presented to her Majesty the Queen.

The Council have much pleasure in announcing that on the advice of the Privy Council, her Majesty acquiesced in the petition, and on the 14th day of November, signed the Supplemental Charter, and ordered it to be sealed with the Great Seal of the Kingdom.

The Council have appointed a Committee to draw up a draft of new bye-laws, which they hope to lay before a general meeting at no distant date.

THE SOCIETY'S CENTENARY.

The subject of the celebration of the approaching centenary of the Society in March, 1904, is naturally attracting considerable attention. After the consideration of various excellent projects (some of which, however, appeared impracticable on account of their expense), the Council have decided to recommend the acquisition of a new garden in the place of Chiswick as being, under all the circumstances, the best and most practical method of celebrating the centenary. A garden for experiment and trial is an absolute necessity for the Society, and Chiswick has recently become so surrounded with buildings, and the atmosphere so heavily charged with smoke, that not only has the difficulty of cultivation enormously increased, but it is feared that the results obtained from the trials are rapidly ceasing to be reliable. It is therefore proposed to issue an appeal to all the Fellows, and to raise a fund for the purchase of a more suitable site for a garden, in memory of the first hundred years of the Society's existence.

The Council fully recognise the advantage of the Society's possessing a hall of its own in which plants, flowers and fruits can be seen by the Fellows under more favourable conditions, as regards light and space, than are possible in the building at present used for the meetings. They do not, however, as yet see their way to its attainment, but will be happy to consider any suggestions concerning it.

NOTABLE LOSSES.

The Council have the sad duty of recording the death of fifty-four Fellows during the year, and among them they regret to find the names

HARPER BROS., *Chartered Accountants*,
10, Trinity Square, Tower Hill, E.C.

In moving the adoption of the report of the Council and the balance-sheet, Sir Trevor Lawrence took the former, and practically dealt with the paragraphs in their order. In doing this salient points were emphasised, but with such a satisfactory condition of affairs nothing particularly new or startling could be advanced. Several tributes were paid to the various Committees and officials, and gratification expressed at the continued excellence of the shows. Speculations had previously been rife as to what the Chairman would say relative to the new Chiswick, but the anxious ones will have to exercise a little more patience, as at this juncture Sir Trevor did not consider it desirable to make public all the doings of the Council in this matter, as such a course might tend to render the work more complicated and difficult.

A few other references were made particularly to the severe loss that the Society has sustained by death during 1899, and the continued increase in the number of Fellows was extremely satisfactory. It was pointed out, too, that the balance of £1751 was the largest the Society had ever been able to show as the result of one year's working. The Rev. Geo. Henslow, V.M.H., briefly seconded the motion, which was further supported by Messrs. J. Cheal, R. Dean, V.M.H., and G. Paul, V.M.H. It was then put to the meeting, and carried unanimously.

It is needless to say that Sir Trevor Lawrence, Bart., was re-elected President, Philip Crowley Treasurer, and the Rev. W. Wilks Secretary ere the meeting closed.

germination keep the frame dark by covering with mats till the seedlings appear, then, of course, the covering must be removed. With newly made hotbeds a chink of air ought to be left on the back of the frame, to allow strong heat and moisture to escape, until the bed begins to decline in heat. During cold nights the frame should be covered with rough straw or mats, and in bright weather give a chink of air for a few days to sweeten the atmosphere and prevent the plants from becoming weakly and drawn, but it is seldom that a great volume of air is at any time needed for forced Radishes. The great point is to get them to grow quickly; they will then be crisp and tender. Sutton's Early Forcing and Extra Early Turnip-rooted are excellent for early sowings, these to be followed by Sutton's Earliest Frame.

In nearly all gardens of pretensions forced Carrots are in demand, and Radishes, and these are frequently grown in the same frame. The Carrots are sown in drills 9 inches apart, the Radishes broadcast, and the latter are ready for pulling by the time the Carrots require more room. Radishes may also be sown between Potatoes planted in pits, but where this is done it is necessary to plant the Potatoes deeply, so that no earthing is needed.

Those who are fortunate enough to have spare frames at the end of February should place them in front of a wall on a warm border

FIG. 36.—A DISH OF RADISHES.

FORCING RADISHES.

RADISHES during winter and spring are always highly prized, and although it is possible to produce them throughout the year, few gardeners grow them in the autumn months, but are content to make their first sowing on a hotbed in December. From that time till the middle of February, in order to secure a continuous supply, it is necessary to sow on a hotbed, for although during seasons when the weather is exceptionally favourable, seed sown in cold frames, or even on warm borders in the open air, will give satisfactory results, it cannot be relied upon, as the roots are often tough and worthless through growing too slowly.

Hotbeds made up in the usual way, by packing in regular layers prepared fermenting materials to a height of 3 or 4 feet, and pacing thereon a frame covered with lights, answer well for Radish forcing. The lights should have a sharp slope from back to front, in order to catch every possible ray of sunshine—an important matter in regard to the forcing of all crops. Light rich soil is necessary to grow Radishes well; this may sometimes be found in the ordinary garden soil, in others it has to be specially prepared. Soil which has previously been used for Cucumbers or Tomatoes, if further enriched with thoroughly decayed and sweet hotbed manure, answers admirably if passed through an inch sieve to remove the rough parts, which if left would impede the progress of long-rooted Radishes. For the Turnip-rooted section a 6-inch layer of soil is ample, but an additional 3-inch layer ought to be employed for the long-rooted types.

The seeds should be sown broadcast, be just covered with fine soil, and the bed then receive a thorough watering. In order to hasten

and sow Radishes in them. So treated the crop will be ready for pulling considerably in advance of sowings made in the open air. Rough planks may also be pressed into service to afford slight protection. These a foot in width are suitable. Arrange them to form the edges of a frame, secure in position by stakes driven into the ground, and at night cover with mats or oiled canvas. Market growers often make a sowing from the middle to the end of February, according to the weather, and when the seedlings appear they are covered with straw, hay, or bracken during frosty nights, and the covering is left on during the daytime occasionally if the weather is frosty. By following this plan they are able to place Radishes on the market at dates which surprise most people when told such produce has been grown in the open air. Light blackish looking soils are peculiarly adapted for growing early Radishes, as they absorb heat, and being thoroughly stored with plant food there is a reserve for the crop to draw upon whenever rapid growth is made under the influence of bright sunshine.

Those who require only a limited supply of early Radishes should sow in boxes 9 inches in depth, and put in a vinery or Peach house just started, or a temporary bed might be formed by placing a few inches of fine soil on the border. From the middle of March till August sowings ought to be made once a fortnight in the open air; then if due attention is paid in regard to watering, satisfactory results are certain to accrue.—H. D.

[For the excellent photographic reproduction (fig. 36), representing in an attractive manner a dish of Radishes, we are indebted to the courtesy of Messrs. Sutton & Sons, Reading, whose selections of this much appreciated salad stand so high in the estimation of connoisseurs.]

FRUIT PRODUCTION—DRYING PLUMS.

A TRULY admirable article is that on page 91. Your versatile correspondent "A. D." touches on various points in a thoroughly practical way, and brings to bear on them a goodly share of that invaluable element, common sense. Whether his concluding proposition is such an important essential as he suggests is a matter on which all persons who are interested in the subject of our home fruit supply will not, perhaps, be equally agreed, at least if he means to say that nothing really worthy of meeting the exigencies of the case will be provided until his plan is carried out in its integrity. A "big" conception indeed it is, but if we wait for its realisation we shall only, it is to be feared, be opening the door still more widely to Californian, Continental, and other fruit growers and dealers to make up the deficiency of our home supplies; still there stands the great educational idea worthily registered in the *Journal of Horticulture*.

NURSERY TEACHING.

Nothing is more true than the scarcity of men who possess the requisite qualifications for managing successfully large undertakings for supplying our markets with fruit of the first quality and in varied forms that shall at once be profitable to producers and satisfactory to consumers. Men of the stamp required cannot be taught in nurseries where trees are raised for other persons to grow and deal with the fruit they may bear. Instruction in budding, grafting, and the formation of trees in their infantile state can be acquired in those establishments, but that is merely touching the fringe of the subject as regarded in its entirety, and with the varied eventualities which must be anticipated and provided for.

SCHOOL AND COLLEGE TEACHING.

Nor can men or women of little or no experience be adequately taught what is requisite to be known on the important industry in question in any schools or colleges at present established in this country. It is true that some of the scientific teachers in such establishments may, by gleaning from books and picking up hints from practical men, formulate theories and lay down general principles more or less sound; but their training does not fit them to be efficient teachers on an essentially practical subject of the important nature indicated.

TRAINING STATIONS.

There may be a few young fruit trees in the grounds attached to some educational institutions, and when these trees are in the hands of skilled cultivators useful lessons can be derived from them in a preparatory way. There are small fruit stations belonging to some of our County Councils, and though these may be of great service locally to owners of private gardens, they are quite inadequate for extensive commercial work such as "A. D." has in view. A good deal was heard at one time about the Duke of Bedford's experimental fruit farm, or whatever it is, and it is to be hoped there is much valuable practical information in store. What little has been published in the gardening Press so far has been of no real service to workers. Gathering, counting, and weighing the leaves, and shading trees with canvas blinds are, from the commercial fruit grower's point of view, mere puerilities, and can only prove, if they prove anything, what has been known for years by experienced men. Almost any amount of money may be spent in proving facts which have long existed. The real substantial want of the times is the demonstration of methods of obtaining the greatest value in fruit from cultivated trees at the least outlay in producing it.

SCHOOLS OF PRACTICE.

Viewing the industry of market, or commercial, gardening broadly, or as embracing the cultivation of fruits, vegetables, and flowers in the open air and under glass, there are no doubt many hundreds of persons who have solved the problem above stated, and some of them in consequence made little (or great) fortunes. Where did they gain the experience that enabled to do so? Can a solitary instance be quoted where it has been obtained by theoretical or scientific teaching alone or mainly? Without any attempt, or desire, to undervalue such teaching, the fact has still to be recorded that nine out of ten, or ninety-nine out of a hundred, of our most brilliantly successful men in any, or all, those occupations, have derived the knowledge that made them what they are from the stern school of practice. The fruit growers of Kent and Hereford, the Grape, Cucumber, Tomato and flower growers of Herts and Sussex, and the vegetable growers of Middlesex, have taught each other, so to say, on the land and in the market, nowhere else, and there are no better or more successful growers in the world than they.

NATIONAL AND COUNTY STATIONS.

If "A. D." were not very much of this opinion he would scarcely have advocated such a large and comprehensive national school of practice as the one referred to of 200 acres with all necessary equipments for carrying out the objects in view. But who is to found it? No society is strong enough to do so. The Government, according to all past history and present prospects, will not do so, and it would be little short of a miracle if any combination of County Councils could be

effected to carry out any such great central scheme. Whether in lieu of several small educational fruit plots in various districts it would not be better to have one large county station is a matter worthy of consideration, if it has not already been considered. From a commercial point of view, or as affording experience for training fruit farmers and purveyors an area of ten acres with all necessary accessories would obviously possess advantages which must be lacking in small experimental plots, while these might be the more useful to a greater number of private growers who could attend and derive practical lessons from them. If twenty counties were to provide areas of ten acres this would be equivalent to the 200 acres suggested. The difficulty in establishing them on this divisional system would be reduced, while it is not improbable the benefits derivable would be increased. But to be of real and actual service a thoroughly sound practical man should have control and be unshackled by a straight laced scientist, who might easily waste both time and money in experiments for his own information and gaining knowledge already possessed by an experienced cultivator. Though competent men are scarce there would not be much difficulty in finding ten or even twice that number by the offer of adequate remuneration.

WORK AND WIN.

Still, in the matter of increased cultivation of fruit for the ever increasing multitude of consumers, there must be no waiting for even the county training grounds propounded. They may never come to pass. How, then, is the required experience to be obtained? It must be had in the same way as those who possess it now obtained theirs—namely, by individual effort, close study, intelligent observation, and persevering work. There is no other safe and sound procedure; no quick and easy way of becoming expert in the important work in question, though an increasing number of people appear to think there is.

A POPULAR FALLACY.

"Where can I send my son for a year to learn fruit growing?" is a common question in these days. If the information is not given you are as likely as not to be regarded as a churl, and hear some such observation as this: "Well, you can at least tell me of some school where fruit growing is taught, or of a few lectures that my son could attend." If this compels a further reply of "No, the subject cannot be sufficiently learned by such means to justify expenditure on land and trees," he will, as a last effort, ask for the names of "cheap books." These you are glad to give, and thus get rid of him. It is difficult to know what to do with such people, who appear to think that everything that is necessary to be known about fruit culture for profit can be "picked up" in a few short lessons. A greater fallacy could not take possession of the mind of man.

DRYING PLUMS—"GLUTS" AND FAILURES.

I have so far said nothing about Plums for drying, and what little I may venture to say now in further encroachment of space will not be in favour of growing them for that purpose. There are some things in which we can excel growers beyond our shores in producing, and some things in which they can excel us. One in which we are extremely likely to come off second best is the prune industry. If we relied on the cheap Plums in "glut" years we should certainly fail, for the simple reason that the fruit from densely overlaid trees consists of little more than water, skin, and stones, and with the water driven out we should have prunes of the worst possible quality. There could be no other result. They would pay no one for drying, as only the lowest of the low prices would be given for them in the buying. Fleishy Plums are requisite for fleshy prunes, and for these to be of the best the varieties must be different from those usually grown in British gardens and orchards.

SEVERAL VARIETIES FOR DRYING.

Some years ago reports of trials in drying Plums at Chiswick were published in some of the gardening papers. Many varieties were tried, and careful note taken of the cost of drying and the value of the fruit after the process was completed. Only one, if I remember rightly, showed a margin of profit, and that was the Fellemberg. This is the Italian prune or Italian Quetsche Plum. It is specially grown on the continent for drying; so are the German Quetsche Plums; also the French d'Agen, Perdrigon Blanc, Perdrigon Violet, and others for the production of first-class prunes. It is doubtful if some of these continental varieties could be grown profitably in England, and such varieties as are now grown could not equal them in a dried state, while much better prices are realised for good samples of ours, green or ripe, for immediate use or preserving. The majority of our soft juicy Plums are not adapted for drying, even in the best condition, and it would be foolish to dry them then, while to dry them when small and "stony," as they are in "glut" years, would surely end in utter disappointment.

THE BETTER WAY.

Much better grow the trees as bushes, and thin the fruits when overcrowded, and then will they, because fine, command a ready sale at remunerative prices. There is always a demand for the "best."—A NOTTS GROWER.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—FEBRUARY 13TH.

THE display in the Drill Hall on Tuesday was a comparatively small one, but this can easily be accounted for by the fact that the weather was most unpropitious. The fog prevented the Orchid growers bringing any specimens to the show.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair); and Messrs. J. Cheal, W. Poupart, H. Markham, Jas. H. Veitch, W. Pope, G. Kelf, A. Dean, S. Mortimer, J. W. Bates, G. Wythes, H. S. Rivers, F. Q. Lane, E. Beckett, G. Bunyard, A. H. Pearson, and Rev. W. Wilks.

Mr. W. Poupart, Marsh Farm, Twickenham, sent a splendid exhibit of Rhubarb. The varieties included Linnæus, Victoria, Hawkes' Champagne, and Daw's Champion. The latter is a cross between Victoria and Champagne, and possesses the very desirable attribute of being much finer than Champagne while retaining the earliness of that variety. The colour is very brilliant when in perfection, and as shown was a very bright rose. It is bound to come to the front. The same exhibitor sent splendid Asparagus and Seakale (silver Knightian medal).

About 100 dishes of Apples were contributed by Messrs. G. Bunyard and Co., Maidstone, and needless to say the fruits were almost without exception in splendid condition. Some varieties that are usually over months ago were in a wonderfully sound state. Particularly conspicuous were Calville Malingre, King's Acre Pippin, Tower of Glamis, Bramley's Seedling, Worcester Pearmain, Small's Prince Arthur, Tibbit's Pearmain, Golden Noble, Allington Pippin, Cox's Orange Pippin, Gloria Mundi, Peasgood's Nonesuch, Gascoyne's Scarlet Seedling, Tyler's Kernel, Lord Derby, Newton Wonder, Annie Elizabeth, Hambling's Seedling, Bow Hill Pippin, Blenheim Pippin, Alfriston, Hoary Morning, Preston Hall, and Reinette du Canada (silver-gilt Knightian medal).

Mr. John Watkins, Pomona Farm, Hereford, staged a grand collection of Apples. As usual, the colour was striking, and the whole of the fruits in excellent condition. Good dishes of the following varieties were staged—Beauty of Kent, New German, Mère de Ménage, Rymer, Wadhurst Pippin, Newton Wonder, Hollandbury, Annie Elizabeth, Blenheim Pippin, Blue Pearmain, Gathlin Pippin, and Claygate Pearmain. It is rather unusual to have fifty dishes of dessert Apples staged in February (silver-gilt Knightian medal).

FLORAL COMMITTEE.—Present: C. E. Shea, Esq. (in the chair); with Messrs. C. T. Druery, H. B. May, R. Dean, J. Jennings, R. Fife, C. R. Fielder, J. Fraser, W. Bain, C. Jefferies, H. J. Cutbush, J. D. Pawle, G. Renthe, E. H. Jenkins, J. James, E. T. Cook, H. Turner, C. Blick, H. J. Jones, E. Mawley, J. F. McLeod, and W. Howe.

Messrs. H. Cannell & Sons, Swanley, occupied a table running the length of the hall with a collection of Primulas of The Lady type. The plants were well flowered, and for decorative value at this season would be hard to beat. The varieties included the old type known as The Lady; Pink Lady, correctly described in the name; Fairy Queen, a beautiful variety, white with a pink flush pervading the petals; Miss Irene, a salmon pink; Mrs. H. Cannell, white, a distinct advance on the original type; Queen of Roses, pale rose; Princess Eva, very free white with a faint blush; and Salmon Beauty, a bright rosy salmon. Mrs. R. W. Cannell, of the true fimbriated type, was also good (silver Flora medal).

Messrs. W. Paul & Son, Waltham Cross, arranged a large table of Clematis indivisa and C. i. lobata. The plants were all growing in 5-inch pots beautifully clothed with foliage and a wealth of white star-like blossoms. The decorative value of this climber is not sufficiently acknowledged at the present time. The group was edged with decorative plants of Grevillea robusta (silver Flora medal).

Messrs. J. Laing & Sons, Forest Hill, contributed a welcome exhibit of Palms, Diacanas, and Crotons, which were brightened with well flowered Azaleas, Genistas, Ericas, Lily of the Valley, and Ferns (silver Banksian medal). Cyclamens were well represented by a fine table from Mr. John May, St. Margaret's, Twickenham. The plants were well grown, and the flowers embraced a wide range in colouring. In most cases the flowers individually were very fine, a bright rosy crimson variety being especially noticeable (silver Flora medal). Hardy flowers were staged by Messrs. Barr & Sons, Covent Garden, which included pots of Galanthus Elwesii, Narcissus, Cyclamens, and a sulphur-coloured Hoop Petticoat Narcissus, also a pretty white form. Lachenalias and Primula obconica grandiflora were also staged.

Messrs. Jas. Veitch & Sons, Ltd., Chelsea, again demonstrated the value of their hybrid Rhododendrons by staging a beautiful box of cut blooms. The most noteworthy varieties were Multicolor, Neptune, Cloth of Gold, Imogene, Triumphans, Lord Wolseley, and Delicatum. Mr. W. Bain, gardener to Sir Trevor Lawrence, Bart., Dorking, staged two vases of winter-flowering Begonias; Triomphe de Lorraine, a deep semi-double red of the semperflorens type; and Boule de Neige, a white of the same form. Messrs. F. Sander & Co., St. Albans, exhibited cut blooms of three new Camellias under popular names—Lady Buller, a deep rose, semi-double, with a few white spots; Lady White, white flaked, red; and Lady Roberts, a rosy variety with a good white picotee edge; in all the stamens were prominent. Mr. W. Bull, Chelsea, exhibited a quantity of Primula blooms arranged on a white

paper, certainly not the most attractive way of staging them. Mr. W. Coates, gardener to Col. Platt, Corddiaog, Llanfairfechan, sent some good cut Primulas with their foliage; the flowers were large and of excellent type. Spiræas were staged by Messrs. Van Waveren and Kruyff, Haarlem. The varieties, W. E. Gladstone and H. Witte, were well flowered, but the weather had caused them to droop very much; both are hybrids of S. astilboides.

ORCHID COMMITTEE.—Present: J. Gurney Fowler, Esq. (in the chair); with Messrs. J. O'Brien, C. Maron, de B. Crawshaw, R. B. White, H. Tracy, H. Little, J. T. Gabriel, H. J. Chapman, W. Potter, F. J. Thorne, E. Hill, J. H. Fitt, W. H. Young, T. W. Bond, C. Winn, W. Cobb, and C. J. Lucas.

Orchids were by no means numerous, simply because of the weather that prevailed. There was not a solitary group, the exhibits

FIG. 37.—CLITORIA TERNATEA. (Page 148.)

being composed of single plants or cut flowers. Amongst the exhibitors were Messrs. N. C. Cookson, Wylam-on-Tyne, who showed Calanthes Phœbe (pink), and Sybil (white), Odontoglossum crispum Mundy-anum, and Cooksonianum; Heath & Son, Cheltenham, who staged Dendrobium Fytchianum giganteum, and Cypripedium Lathomianum giganteum; L. Linden, who exhibited Cypripedium Schusterianum, Odontoglossum Ruckerianum rubiginosum, and O. crispum Goliath; W. Cobb, Tunbridge Wells, who sent Lælia anceps Stella and Sanderiana, and Cypripedium Bassano; F. A. Rehder, Gypsy Hill, Cypripedium Faverger; C. J. Lucas, Horsham, Dendrobium macrophyllum Richardi; C. Maron, Lælio-Cattleya Ernesti pallida, and L.-C. Bertha Fournier var. splendida; R. Brooman White, Ardarrach, a splendidly formed Odontoglossum triumphans, with other Odontoglossums; and Captain Holford, Cattleya Trianae, Westonbirt variety.

CERTIFICATES AND AWARDS OF MERIT.

Lælio-Cattleya Bertha Fournier, var. *splendida* (C. Maron).—This variety is superb. The magnificent lip is rich velvety crimson

flushed with purple. The sepals and petals are rich rose (first-class certificate).

Odontoglossum crispum Mundyannum (N. C. Cookson).—This is a superb variety; the flower is round and the organs of great breadth and substance. The colour is white with immense chocolate brown, there being also blotches of similar colour. The lip is fringed with red brown markings (first-class certificate).

Rhubarb Daw's Champion (W. Poupart).—This is a variety that must become immensely popular for forcing and general purposes (award of merit).

THE YOUNG GARDENERS' DOMAIN.

RHUBARB.

FEW vegetables force more readily than Rhubarb, provided strong, well ripened crowns are obtained at the outset. For the earliest supply a few roots should be lifted and placed in a Mushroom house, warm pit, or even a cellar, while a succession may be maintained by forcing on the plantation in the old fashioned way with tubs packed round with fermenting material, composed of long stable litter and leaves. Where the roots are well established large quantities of stalks will be produced, but as soon as the crowns show signs of weakness the tubs and forcing material must be removed, and the ground made neat and tidy by forking between the rows.

As has been said, the forcing of Rhubarb is very simple where good crowns are at command, and to produce these is an all-important operation. The position of the Rhubarb plantation is frequently in an out of the way situation, shaded by trees. Such a position is altogether unsuitable, as this plant revels in highly cultivated and properly enriched soil; farmyard manure dug in during the autumn is most advantageous. The planting should be left until the early part of March, then stations ought to be made 2 feet apart and sufficiently deep to avoid crippling the roots in planting; a space of 3 feet between the rows must be allowed. The soil should be well worked round the roots, the crowns being just buried; the surface may then be afforded a mulch of short stable manure, which can be forked in at a later date. The stalks must not be pulled the first season, as this weakens the plants.

Propagation can be carried out either by division of the roots or by procuring seeds, and the former, I think, to be decidedly preferable to the tedious operation of raising roots from seeds to form plantations. The varieties usually grown in gardens are Royal Albert, an early one, also Paragon, both of these are superb colour, and Victoria, an excellent robust growing Rhubarb, is a great favourite for general purposes.—F. W. G.

EARLY STRAWBERRIES.

To obtain good runners for forcing, young stock should be planted at the latter end of August or the beginning of September. A good plan to adopt for this is to have the rows alternately 2 feet and 18 inches apart, and the plants in the rows 12 inches asunder, thus giving plenty of room when layering takes place, to stand the pots between the rows that are 2 feet apart, while the others will answer for watering. During the growing season keep the border free from weeds by hoeing between the rows occasionally, and if the weather become very dry an occasional watering will considerably benefit the plants. Remove the flower stems as they appear, and any plant that is not showing bud should be plainly marked, and if on a second inspection it still fails to flower it should be thrown away.

About the first week in July layering must commence, and prior to this all preparations should have been made, such as getting the compost ready and the pots cleaned. The soil may consist of loam, Mushroom bed refuse, and a little lime. Some growers prefer layering in the fruiting pots, but as there is a danger of the soil destitute of roots becoming sour, I think the small size is better. The pots must stand level to facilitate watering when required, and the runners should be secured to the soil in the pots, either by pegging or a small stone, to keep them in place until roots have formed. When the layers are rooting through the bottoms of the pots, they should be detached from the old plants and stood in a rather shady place.

When this stage is reached preparations must be made for putting the plants in their fruiting pots. They can be potted in two sizes, 5 inch for the earliest ones and 6 inch for the later varieties. Have the receptacles thoroughly cleansed and well drained, and a little soot placed on top of the crocks to prevent worms from getting into the soil. The compost must be prepared, and if the loam is in any way dry it should be thoroughly watered a few weeks before potting commences. The mixture may consist of loam cut or broken into pieces; Mushroom bed refuse, a little lime, some suitable fertiliser, and a dash of bonemeal can be added. Judgment should be exercised as to the quantity of Mushroom bed refuse, as the loam varies so much in texture that exact proportions cannot be given.

Let the potting be firm, using a rammer to attain this end, and have the base of the crowns just level with the soil when finished. The pots should be filled to within half an inch of the rims, as this will leave room for watering. After potting the plants should be stood in a rather shady position for a few days, to give them a better oppor-

tunity to make fresh roots than would be the case if they were in the full sun; also give each one a thorough watering. A good place to stand the pots while the plants are growing is on walks where they can get the full benefit of the sun. Watering must be carefully done, only giving to those that require it, and it will benefit the plants if they are syringed in the evenings after hot days. Remove all weeds and runners as they appear.

The plants that are potted for the earliest forcing should have one crown, while the later ones may have two; all surplus crowns ought to be removed in the early stages. As the winter begins to appear preparations should be made for protecting the plants against the heavy rains, snow, and frost. The best plan to adopt, if the room can be spared, is to stand them closely together in frames, where the lights can be taken off or put on at discretion. Where there is not sufficient space for this the pots should be stacked one on the other on their sides, and ashes placed between them. Do not let the plants become thoroughly dry, or, on the other hand, very wet.—P. R.

(To be continued.)

HARDY FRUIT GARDEN.

Planting Fruit Trees.—When the autumn planting of fruit trees is impracticable, or having been commenced could not be completed, the work may be carried out now. The chief essentials are a comparatively dry condition of the ground, and the soil previously well prepared and in the condition which insures its working properly. The majority of fruit trees are still inactive, but in a very short time buds will be bursting and the roots will be originating new fibres. It is therefore advisable to plant as soon as possible, especially in the case of trees which have to be purchased.

When trees are received for planting it is a most important matter to lay the roots in the ground without delay, as exposure of the fibres is very injurious, and renders a fresh start somewhat difficult. Should the roots be very dry it will be advantageous to plunge the trees in water if the weather is mild, leaving them for a day or two, then lay the roots in soil to await planting. When the trees arrive in frosty weather it is best not to unpack them, but lay them in a cellar where frost does not reach until the weather breaks.

Forms of Fruit Trees.—The forms of trees best adapted for the position must be chosen. Standard trees are only suitable for large plots. Pyramids and bushes are adapted for more restricted spaces. Fan-trained, horizontally trained, and cordons are specially suitable for wall culture.

Distances for Planting Fruit Trees.—The form of tree and the stock upon which it is worked regulate the distance of planting. Standard trees of Apples and Pears for large plots may be planted 30 feet apart. The former are on the Crab stock, and the latter on the Pear stock. Pyramid and bush Apples on the Crab stock, and Pears on the Pear stock, make large and vigorous trees, hence must be planted 12 feet apart. The same forms of trees with Apples on the Paradise stock and Pears on the Quince stock only require 6 feet space between. They may be closer together than this if lifted and root-pruned. Horizontally trained wall trees may be 15 feet asunder; fan trained trees the same distance. Upright or oblique cordons of Apples and Pears should be 2 feet apart. Single cordon Gooseberries and Currants may be a foot apart.

Preparing the Holes for Planting.—The proper position for planting having been fixed, excavate the soil and form a shallow wide space for the reception of the roots, as it is important that they be spread out to their full extent. The centre of the hole may be raised rather higher, making a slightly convex mound.

Pruning the Roots.—Before the trees are planted finally the whole of the roots must be examined, and those which have been torn or injured in the process of lifting must be pruned to healthy portions, making slanting cuts from underneath upwards with a sharp knife.

Planting.—Some fine soil ought to be at hand for spreading over the roots. It may consist of good loam mixed with dry wood ashes or burnt refuse. Place the tree in position and spread out the lower layer of roots, and secure them in their proper direction by sprinkling soil over them from the stem outwards. The next layer of roots may be treated the same until all are securely fixed, the upper layer being covered 3 or 4 inches.

Staking and Mulching.—The standard trees ought to have stakes placed to them as soon as planted, and be secured with some soft ligatures which do not injure the bark. Sacking or strong cloth wrapped round the stem is the best, and the whole made properly fast with pliable copper wire. Mulch the soil over the roots with littery

manure. Heavy solid manure is not required, as it tends to keep the soil cold in spring, whereas it should be able to receive the warmth of the spring sunshine. Also attach the proper names to each tree as planted with some legible permanent labels.

Planting Bush Fruit.—Where it is intended to plant Gooseberries and Currants the work ought not to be delayed, as they will shortly be pushing into growth. Liberally manured and trenched ground should be prepared. Two or three-year-old bushes may be planted at a distance of 6 feet apart. Single cordons for walls or fences should be inserted a foot asunder. Those which are to be trained to three stems must be 3 feet apart. Black Currants are only grown as bushes because of the necessity of taking the crop from shoots of the previous year. It is not profitable to grow Black Currants as cordons, or to subject them to the same course of pruning as is accorded to Red Currants.

Japanese Wineberry.—This hardy fruit-bearing shrub bears small red fruit of a useful character. The shoots may be trained to a trellis, similar to Raspberries. The pruning consists in cutting away the previous year's shoots that have borne fruit, retaining the young growths, which may be shortened to 5 feet or less. The plants require full exposure in a sunny part of garden, and should be planted in soil of a rich character, freely mulched with manure in summer to maintain the ground moist and cool. Liquid manure is also of assistance in encouraging strong growth.

FRUIT FORCING.

Cherry House.—The trees started in December and forced before will be going out of flower, and the fruit having set may have the night temperature slightly advanced. Trees started at the new year and forced for the first time are rapidly unfolding their buds. Before the flowers expand the house should be fumigated, as aphides are almost certain to be present, but the fumigations must be done carefully, or the blossoms will be more or less injured. Keep water from the blossoms, but secure a genial atmosphere by damping the paths and borders occasionally.

Peaches and Nectarines.—*Earliest House.*—The trees must be syringed every morning and afternoon during sunny weather to check red spider. If, however, the weather be dull the syringing must be practised early in the afternoon, so that the trees may become fairly dry before night, or if that does not take place the afternoon syringing ought to be dispensed with, damping the paths and borders instead, as keeping the trees dripping with water through the night causes weak growths and thin foliage. Continue disbudding, taking care to leave a growth at the base of each bearing shoot and another at its extremity, or at least level with the fruit. The shoots retained for attracting the sap to and supporting the fruit should be stopped at the third leaf, but the basal shoots must be trained to take the place of those now bearing fruit. The growths on extensions must be left 12 to 15 inches distance apart to form the bearing wood of the future and for framing the trees. Ventilation must be carefully done in severe weather, avoiding currents of cold air. When the fruit is the size of small marbles thinning may proceed. Water inside borders as required, using liquid manure, which will assist the trees in swelling the fruit, especially in the case of weakly trees long subjected to forcing. Healthy trees will not require any active stimulants, excessive vigour being unfavourable to the fruit safely passing the stoning process.

Second Early House.—Trees started early in January have the flowering rather prolonged in consequence of the somewhat inclement weather, and fertilisation may still be practised, brushing the flowers, or distributing the pollen by shaking the trellis. Admit air on favourable occasions, freely when the external air is mild, avoiding cold currents in severe weather, and providing a little ventilation constantly at the top of the house. The night temperature should be maintained at 50°, and 5° less on cold nights, 55° by day artificially, and 60° to 65° from sun heat, not allowing a rise to 65° without a free circulation of air. Syringe the trees when the flowers fade, but only moderately, as excessive moisture facilitates wood growth more than the development of the fruit. The moisture will assist the fruit to throw off the remains of the flowers. In dull weather a genial condition of the atmosphere may be secured by damping the surfaces rather than the trees in the morning and early afternoon, an occasional syringing early in the day sufficing to keep red spider in check.

Houses Started Early in February.—The trees are now coming into flower. Syringing over them must cease—indeed, it should be discontinued when the blossoms show colour. Nevertheless, maintain sufficient moisture by damping the paths and borders two or three times a day as weather may be advisable, avoiding a close stagnant atmosphere. If the flowers are numerous, thin them by rubbing off those on the back or under side of the trellis, which will strengthen the remainder. Examine the trees closely, and if there are any aphides fumigate with tobacco or vapourise with nicotine, so as to destroy them before the flowers expand. Continue the temperature at 40° to 45° at night and 50° by day, above which ventilate freely. When flowers expand raise the temperature to 50° at night, 55° by day artificially, and 60° to 65° from sun heat, with free ventilation. On cold nights the temperature may fall to 45° or even 40°, also 50° by day in dull cold weather, allowing a little ventilation constantly at the top of the house.

Strawberries in Pots.—The earliest forced plants will need the fruit supporting by forked twigs of Birch thrust into the soil, the stem of the truss being placed in the fork, so that the fruit hangs clear of the pot or soil. It will thus acquire colour and quality better, and be in less danger of damping. Later plants having the fruit fairly set will need attention in removing all deformed fruits, leaving the most promising and in number proportionate to the vigour. The swelling must be aided by copious supplies of liquid manure. The temperature should be 60° to 65° at night, 70° to 75° by day, with gleams of sun and moderate ventilation, advancing 5° to 10° on bright days. Avoid drying currents of air, as they injuriously affect the swelling of the fruit. Examine the plants twice a day for water, giving it only to those in need of a supply, and always so as to moisten the soil through the drainage. Keep successional plants free from aphides, taking care to have them quite clean by the time the flowers open. British Queen and other late forcing varieties may now be introduced, at the same time starting proportionate quantities of the midseason or second early varieties, such as Sir Joseph Paxton, to maintain the succession of fruit.

THE BEE-KEEPER.

CHANGING FLOOR BOARDS.

WE have always advocated the use of loose floor boards to hives, and though our stocks have increased in number, entailing more work in the apiary, we do not begrudge the time occupied in changing the floor boards as often as may be considered necessary. It is important that this matter receive due attention at this season, when rain, sleet, or snow is of daily occurrence, as however carefully a hive may be made there is often an accumulation of moisture on the floor board. This is usually found at the corners of the hive.

The plan we adopt is to have all our hives of the same size. The floor boards are thus interchangeable, and as we always have some extra ones on hand there is no difficulty in finding a dry board when required. We have recently placed dry floor boards to the majority of our hives. It was not all done at once, but a few minutes sufficed to do half a dozen hives, the number of dry boards we had in readiness. The dry board was first placed on the stand by the side of the hive, which was lifted bodily with both hands and placed on it. The original board was removed and the hive placed in position. This was continued from one end of a long row of hives.

The floor boards thus removed were thoroughly cleaned and dried, and were then used for other hives, an operation which takes up much less time than some bee-keepers would imagine, and adds greatly to the well-being of the bees. If the floor board is fixed to the hive it is impossible to attend to them in this manner, as it would not be advisable to remove the combs and disturb the bees at this season, although in many instances if such hives were examined they would not be found in a satisfactory condition.

REDUCING ENTRANCES.

After the spell of changeable weather, with little sunshine a higher temperature will probably prevail. Bees will be continually on the wing, and breeding will commence in strong colonies. It will, therefore be advisable to reduce the entrance to all the hives, so as to keep them as warm as possible. As we have stated in previous notes, the whole of our hives have their entrances left fully open throughout the winter. At this season, however, we reduce them to 1 inch or less. It is a good plan to do this after dry floor boards have been given to each hive, they will then not require removing until the spring is advanced, when a thorough overhaul of all the hives may be made.

There is another reason why the entrance should be reduced during the spring months, not only for warmth, but to prevent robbing. If there is a weak colony, and it will always be found that some stocks are stronger than others at this season, it will be attacked and all the stores removed before the bee-keeper is aware of it. The bees stand no chance if the entrance is fully open, but when it is reduced so that only one bee can pass at a time they are able to protect their stores, and probably by midsummer they will be in as good condition as the colony, which at this season appeared so much stronger.

On removing the floor boards a great difference will be found in them. Some will be quite free of dead bees, whereas others will have numerous dead bees nearly blocking the entrance. This will arise from a variety of causes, but it is more often observed after a long spell of cold dull weather, when the bees have been confined to their hives for several weeks.—AN ENGLISH BEE-KEEPER.

•• All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

The Onion Maggot (*F. W. R.*).—It is difficult to prevent the attacks of the Onion maggots. The insects pass the winter in a pupa state in the ground, and in this form are so well protected by their cases that it is not easy to destroy them. Ammoniacal liquor from gasworks, and solution of paraffin, of the strength of an ounce of oil to a gallon of water, and poured over the ground, are more or less effective, and also act as manure. It is well to have Onion beds as far distant as possible from where the crops were last grown and attacked. It is a good plan also to dig the ground deeply a day or two before sowing, as then many of the pupa cases are placed so far below the surface that the flies cannot readily emerge from them, and thus deposit eggs for producing future crops of maggots. Very heavy dressings of lime and soot are also advisable before sowing. Deep drills drawn and filled with wood ashes, and in these sowing the seed, is a method that has been successfully adopted by some cultivators. Plants raised in boxes under glass and transplanted often escape injury by the enemy.

Clitoria ternatea (*W. Raby*).—This belongs to the Leguminosæ, and is a handsome blue flowered plant. It is seldom seen in gardens, and yet the brilliant colour of its flowers ought to render it a general favourite. According to Paxton "this handsome plant was first brought beneath the notice of botanists and floriculturists as long ago as the year 1739. From that period down to the present it has been erroneously considered by many as an annual species, and slighted accordingly. Such an opinion probably had its rise in the mode of culture which has occasionally been pursued. Instead of treating it as a stove plant, it was, from the facility with which it ripens seed, raised anew each spring as a half-hardy annual, and transferred to the open flower border, where it was destroyed by cold. "From circumstances similar to the above, this plant has not been an isolated example of false notions being imbibed respecting its habits. Notwithstanding the evident bent of cultivators rather to supply a plant with too high a temperature than to suffer it to be too much exposed, here is an instance, out of several others that we might mention, in which a contrary method has been practised. When, on the other hand, it is retained in a stove, to which a moderate amount of heat is furnished, it assumes quite another appearance. The stems, instead of perishing yearly, become shrubby at the base, the lower leaves remain through the winter without withering, and it is the upper branches alone that exhibit any signs of decay. Its natural habit is, therefore, decidedly suffruticose, and that to which it has been reduced in our gardens is simply a constrained one."

Taking Cuttings of Laurels (*Mrs. S.*).—The latter part of September is the most favourable season for this operation, as the cuttings then have time to callus before the sharp weather sets in, and are thus prepared to emit roots early in spring. We have frequently inserted many thousands of cuttings at the time named, usually the last week in September, and had plants fit for transplanting the following season, either further apart or into permanent positions. The cuttings, 9 to 12 inches in length, should have a heel of the two years' wood, say a couple of joints, have the leaves trimmed off half the length, and be inserted two-thirds of the length of the cutting in the soil, firming the ground well, but not excessively about them. The cuttings may be placed in rows 1 foot apart and 6 inches asunder in the rows.

Growing Ixias (*A. B.*).—Ixias are not particularly difficult to grow in pots. The bulbs should be potted rather firmly in sandy loam and leaf soil in October, placing about half a dozen in a 5-inch pot, and covering with an inch of soil. The pots ought to be stood on and plunged in ashes or cocoa-nut fibre refuse in a cold frame, and if the soil was moist when used little water will be required during the winter. When the flower spikes appear more water may be given, affording the plants plenty of light and air, but avoid cold cutting draughts. They may be moved to the greenhouse after they are advanced for flowering. After flowering growth should be encouraged by watering for a time; but that complete, gradually ripen them off, and after the leaves decay they should be kept dry until autumn, when they may be shaken out and repotted.

Clay and Cow Manure for Grafting (*D. F. J.*).—We consider this as good as ever for the purpose, the clay having been beaten into a paste with about half the quantity of cow manure and horse droppings. Some amateurs do not care to go to so much trouble in preparing the pigment. Grafting wax is the simpler process, but it costs money, whereas grafting clay entails no outlay in many cases but the labour, and amateurs have often to consider ways and means. The following recipes, taken from "Profitable Fruit Growing," are excellent for preparing grafting wax:—"1, To be used warm. Resin, 8 parts; tallow, 3 parts; red ochre, 3 parts; Burgundy pitch, 1 part. First melt in an iron pot the resin, add the tallow, and lastly the red ochre; stir well together, but do not make nor use too hot. 2, To be used cool. Equal parts of yellow wax and turpentine, with half as much Burgundy pitch as either, and half as much mutton suet as pitch. Melt all together, mix thoroughly, leave them to cool, then form into small balls, and use when required. The object of grafting wax is to exclude air, and if any cracks appear they must be promptly filled, leaving a smooth surface."

Artificial Manure for Early Potatoes to be Followed by Celery (*J. F. A. B.*).—Rape seed meal (oil extracted), 6 cwt.; bonemeal (4 per cent. ammonia and 45 per cent. phosphate of lime), 3 cwt.; sulphate of potash (97 per cent. purity) 1 cwt., mixed, per acre, would be a suitable fertiliser for a light soil with a subsoil of gravel. Muriate of potash would act more quickly, but it is not wise to use it in spring on land containing lime, as there is a liability to form chloride of that element, similar remarks applying to kainit. Something will be left over for the Celery, though we suppose you will employ manure in the trenches for this crop, and a little nitrate of soda sprinkled along the side of the plants in the trench will give them a start, but it must not be used after August or early September. Soot also is an excellent fertiliser for Celery. The Celery crop will certainly tend to deepen the soil or rather loosen it for the proposed following on with Asparagus, manuring for this with Mushroom bed refuse.

Preparing Ground for Asparagus (*Idem*).—The formation of an Asparagus bed from Mushroom bed refuse, according to our instructions in your particular case—namely, bastard trenching the ground, putting the manure in the bottom spit, which was simply dug in with a fork, is correct, more manure being mixed with the top soil. It is immaterial whether you fork over the beds or not before planting, though it would not do harm, and would perhaps do good, by mixing the manure better or more evenly through the soil. It is not essential to bring some manure to the surface, though we have found it excellent practice to mulch the bed after planting with about an inch thickness of rather fresh manure. The planting of yearling plants 2 feet apart each way—that is, in rows 2 feet between and 1 foot from the sides of the alleys or bed, this being 4 feet wide, is proper to produce fine heads. If desired to have early returns the plants may be a year older, some plants being weak at one year old, though others are quite as strong as thickly grown two years old. A row of early Potatoes may be taken in the "gangways" or alleys between the beds, or, if you prefer, Cauli-flowers. It would hardly do to plant Dwarf Kidney Beans on the beds between the Asparagus plants, though we have practised it. If you adopt the plan we should recommend Ne Plus Ultra Bean. The point is not to have the Beans so thick as to crowd the Asparagus, secure the crop and remove the plants as soon as possible, so as not to prejudice the second growth of the permanent crop.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh

grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (R. E. W.).—1, *Garrya elliptica*; 2, *Spiraea palmata*; 3, *Thuiopsis dolabrata*. (M. G. C.).—1, *Cypripedium Spicerianum*; 2, *C. villosum*; 3, *Cattleya Trianae*; 4, *Euphorbia splendens*; 5, *Ficus repens*. (Inquirer).—1, *Grevillea robusta*; 2, *Anthericum variegatum*; 3, *Ophiopogon Jaburan variegatum*; 4, *Freesia refracta alba*; 5, *Odontoglossum crispum*, poor variety. (P. A. J.).—*Cyperus nepalensis*; *Cypripedium insigne* Maulei.

HOW TO SATISFY THE MALTSTERS.

BREAD is the staff of life, Barley the body of the beer, and it is a provoking and aggravating thing to see English beer which has not an English body; in other words we wish to see malt made from our own Barley rather than from that of our continental growers. Well, but the big brewers are masters of the situation; they lay down certain rules, and from those rules they will not swerve a hair's breadth. They will have Barley of good colour, good shape, fine skin, of one or two fixed varieties that have been proved to be reliable for malting. Failing all this, they take their money and send their buyers far afield, with instructions to bring back at any price a certain article and that alone. As the field is wide they get what they require, and hold themselves under no obligations to trade at home. Hence the disappointed grower has to do what best he can, either sell at low prices to small maltsters who are not so particular, or to dealers who either sell the Barley as meal, or, combining it with other ingredients, form a feeding cake. The farmer has another alternative, and that is, of course, to use the despised grain at home for his stock. But that is not quite what he wants; he would prefer hard cash, but this year in nine cases out of ten he has had to do without.

Of course we all know of what tremendous importance the "season" plays in the comedy, or rather tragedy, of Barley growing, and the "season" we cannot alter. There are many little points, however, that we can adjust, and it is well we should just recall them before sowing the Barley crop of 1900. We have treated of the Barley crop times and times again; it is a subject to which we must ever recur if we do our duty towards the readers of "Home Farm."

We are learners ourselves, and shall be till the Daisy grows above us, and we attentively read all we can find that bears on the agricultural subject. Some time ago we remarked on an excellent article "On the Quality of the Barley Crop," by Professor Wrightson, and as that article covers the whole subject so well, and is so in accord with all our humble efforts and all our observation, we will, with the Professor's leave, recapitulate the main points of his remarks here. We are all agreed upon the first point, that without quality we have nothing; that is, we need expect no great maltster to look at our Barley samples unless those samples are of the best.

The first two requisites are soil and climate. If you possess neither the one nor the other pray turn your attention to some other industry. You can easily prove whether or not the soil is of the right kind. Have you luck with your sheep, that is with reasonable management? Can you grow good Turnips? If you answer those questions in the affirmative, you may sow Barley and hope for a decent sample. As for the climate, well warmth and dryness are the two principal essentials. There are districts in England that have been noted for fine Barleys for generations. There is something in the soil that no cultivation puts there, and which is not supplied by the most cunningly devised of fertilisers.

If there is one crop more than another dependant on the season it is Barley, and this is a factor that upsets our cleverest calculations. One man says, "Sow early. My best crops were from early sown seed." The next man says, "Yes, but what about that Barley on the last sheepfold? Where did you see better?" Both men are right; right for the year and the season of which they are talking. After all, it is a sort of game of "hit or miss," and our best laid schemes disappoint us. We think if we took the opinion of a room full of good farmers, the majority would say, "Sow early;" the plant then has a chance of getting away from frosts and early summer drought. But, again, we have seen such forcing weather end of May, that the later sown Barley has more than overtaken the earlier. Our idea is this—never lose an opportunity if land is fit and weather favourable, get your

Barley in by all means early; it is off your mind, and there is more than enough work for horses and men later in the season.

Then, what is "early?" That opens up another question. Is the Barley to be after Turnips or after Wheat? This leads up to the condition of the land. We have seen, and you have seen, and will again see, crops of what ought to have been good Barley ruined by too much kindness. The land has been too fat, too rich; the crop has been too big by half, and has all gone down to the ruin of quality. Now, if land be in such very good fettle, we shall get a better sample after a crop of Wheat has rather drawn off the extreme richness, and therefore it would be possible in this case, given an open winter, to get in the seed in January. After Turnips you cannot be so "forrard," but don't lose a chance, following, of course, the custom of the district. Is it necessary to speak of a fine well prepared seed bed? This is most essential.

What shall I grow this year? Well, is it to be maltster or miller, quantity or quality? We have seen a good bit of Barley trade this last autumn, and there was only one variety that the maltsters would look at—"Chevalier." None of the others approach it with regard to malting qualities. There is some subtle difference about it we laymen cannot understand; however, it is what they want and what they will have, or no other. Many of the other varieties yield better, and are therefore valuable in that respect. Everyone has his own private idea as to the proper quantity to sow per acre, and the sort of grain. Quantity differs from $2\frac{1}{2}$ to 4 bushels—here again general custom must be the guide. The seed should be good and sound, and of an approved variety. Some, again, are in favour of "hinder ends" or small screenings, others prefer seed from the bulk, which, of course, if not any better, is much more expensive.

If Barley is difficult to grow, it is also difficult to harvest; it is apparently ripe ten days before it is really fit. Farmers are often in too great a hurry to cut, as there is such a danger of ripe Barley "necking" should a high wind get up. It is wonderful, too, how a shower when the corn is in stook will improve the quality. If the season be at all "catchy," care should be taken in the stacking. Hedgerow stooks must not be mixed pell mell with those from the drier and more exposed parts of the field; indeed, during leading the master or an experienced hand should never leave the field. A little care then saves infinite trouble afterwards, for no machine has yet been invented which will remove discoloured grains.

As to the use of artificial manures, there are many fallacies abroad. Sometimes a crop wants a little help, at others the money so spent is worse than wasted. A dressing of superphosphate increases the weight, and 1 cwt. of nitrate of soda or sulphate of ammonia will improve the vigour of the entire plant. Lastly the Professor writes: "It will be found that previous manuring, and general good cultivation carried out during a series of years, will produce a better result than any immediate dressing of fertilising matter."

WORK ON THE HOME FARM.

Farmers are still marking time, for there is little chance of making good headway with farm work. We have had a heavy fall of snow, which has nearly all melted and left the surface very wet, and we are now having severe frosts, which will do good if the weather will only keep fine. To-day the land is too hard for the plough, so muck-leading is the only available occupation. Some of the yards are now too full, and need relief from the great depth of manure, so this is necessary work, otherwise not much is gained by carting the stuff into hill, from which it will again have to be forked into carts when it is time to drill Swedes. Of course, if the field lies a mile or so from the yard, which is often the case in some districts, there is a distinct advantage in getting it out now. The extra labour of carting muck long distances and bringing grain crops in is really an extra rent put on the land. Few men when taking farms take sufficiently into consideration the average distance of the arable fields from the farmstead. The difference in value between extreme cases may be 10s. per acre or more.

Wheat holds its own but does not grow much; it has had quite enough moisture. We saw the corner of one field looking in a very bad state the other day; the hounds had crossed it, and apparently the whole "field" had crossed this particular corner in a body; about half an acre seemed to be quite ruined, and much as if a heavy drag had gone over it. Cases of thoughtlessness such as this make farmers look askance when they see hounds coming. Being in the near neighbour-

hood of a large city, perhaps the field may have been composed largely of persons ignorant of the appearance of a Wheat field.

Mangolds are now fit for use, and are already being drawn upon. They must be well husbanded, for it is a long time to grass yet. We notice that complaints have appeared in the papers of the Government having bought forage (for the war) abroad instead of at home. We fancy all our English hay will be required at home, and certainly so if we are to have any sharp weather. Ewes are healthy and doing well, lambing reports are favourable, but, so far, the fall of lambs is small. Very early twins, however, are not an unmixed blessing, as a very good mother is required to get a pair fit for early killing.

TOBACCO GROWING.—Many years ago Tobacco was pretty extensively cultivated in Ireland, and to this day fields are met with here and there, still known as the Tobacco field. Vexatious restrictions were however, put on the growing of it, and its cultivation ceased altogether, Col. Everard, of co. Meath, who is always to the fore in any useful agricultural experiment, grew some Tobacco last year, and it has been on view at the offices of the Irish Agricultural Organisation Society. The samples shown were very good, and if the cultivation of "the weed" were permissible, it would seem to open up a vast field of enterprise for farmers and others in this country. The climate of Ireland may be a trifle on the damp side some years, but the Tobacco plant seems to thrive luxuriantly. The specimens on view were grown on two experimental plots, measuring each 49 square yards. In one case the plot was manured as an ordinary Turnip field, and in the other heavier manuring and doses of liquid manure were used. The crop was harvested on the 29th of September, and took six weeks to dry thoroughly. When quite dry the crop from the first plot weighed 14 lbs. 12 ozs., and from the other 20 lbs. 15 ozs. The revenue duty amounted to 2s. 8d. per lb. The 35 lbs. of leaf produced 33 lbs. of manufactured Tobacco, and at this rate the average produce per Irish acre (which is much larger than the Statute) would be 2640 lbs. Col. Everard calculates that the gross value per Irish acre, with Tobacco at 4s. per lb., would be £528, from which £352 would have to be deducted for excise duty, and £44 for cost of manufacture, leaving a balance of £132 for rent, labour, and profit.—("Rural World.")

THE R.S.P.C.A. AND WOUNDED HORSES.—The Royal Society for the Prevention of Cruelty to Animals has made itself rather ridiculous, in connection with the war, by advising the Government to send a special corps of horse slaughterers to prevent unnecessary suffering in the field on the part of wounded animals. No one feels more for a wounded horse than does the trooper or driver, as the case may be, and no court martial is on record of a man being charged with destroying a horse he thought too much injured to recover. This is saying a good deal when it is remembered that a properly qualified and military-trained veterinary surgeon is detailed for duty with each cavalry regiment and depot of artillery, among the transport corps, and at the base. Each troop has its farrier sergeant, and each regiment a farrier major, all instructed in veterinary matters and at the disposal of the veterinary officer, who has an orderly told off each day or week for his own service. This man carries in special wallets the means of first aid as well as last aid, and the officer or his orderly settle the hopeless cases with the revolver on the spot. It was, however, decided at the Geneva Convention that veterinary officers should not come under its protection, so, though not being combatant officers, they are, nevertheless, liable to capture, and cannot afford aid to the wounded at the risk of the doctor being himself taken prisoner. This is very prettily pointed out in the courteous reply given to the R.S.C.P.A., which is recommended to get the Convention extended to include vets and their orderlies before asking to add useless non-combatants to an army by introducing knackers.—("Farmer and Stockbreeder.")

THE DISINFECTION OF RAILWAY HORSE-BOXES.—A memorial has been addressed to the Board of Agriculture by masters of hounds, owners, breeders, and trainers, and others who are interested in high-class horses, on the subject of the disinfection of railway horse-boxes. It states that there has been for many years past a serious prevalence of infectious ailments in the various studs and stables of this country, leading to great and increasing loss through the deaths of valuable horses and mares, and that such diseases are in a large measure spread through the neglect of the railway companies to cleanse and disinfect horse-boxes after use. It is pointed out that the existing regulation, requiring the companies to sweep out the horse-boxes and to wash the mangers with water, is wholly insufficient to disinfect such boxes by destroying the germs of disease, but, even so, the regulation is seldom, if ever, given effect to by the companies. Vast numbers of horses from America and elsewhere are, it is said, brought every week to this country without any restriction as to their freedom from disease, and these are conveyed in horse-boxes by the railway companies and distributed throughout the country, such horse-boxes being subsequently used without sanitary precaution for the conveyance of other horses, no matter how valuable. The memorialists ask the Board of Agriculture to take the whole subject into consideration with a view to (a) improving and rendering more effectual the prescribed method of disinfecting horse-boxes, whether by the use of Formalin or otherwise; (b) compelling the railway companies to carry out scrupulously the regulation at present existing, and any new regulation that may be made.

BARR'S SEEDS

OF FINEST SELECTED STRAINS AND TESTED GROWTH.

NOVELTIES & SPECIALITIES FOR 1900.

Barr's Golden Wax-Pod Dwarf Butter Bean; the fleshy pale yellow pods run to sin. long, are stringless, and of delicate flavour; it is a marvellous cropper and very early. Per pint, 1/9; per quart, 3/6.

Barr's Lightning Runner Bean, a remarkably prolific Runner, and the earliest of all, bearing numerous heavy clusters of long fleshy pods of a fine delicate flavour; a valuable acquisition. Per quart, 2/6.

Barr's Covent Garden Beet, dark crimson flesh, fine flavour, medium size. Per packet 6d.; per oz., 1/3.

Barr's Hardy Winter White Broccoli, a magnificent Broccoli; should be sown from end of March to May for a succession. Per packet, 1/-; per oz., 2/6.

Barr's Little Queen Cabbage, of delicate flavour; highly recommended. Per packet, 6d.; per oz., 1/6.

Barr's New Intermediate Carrot, superior medium long Carrot, of a rich red colour and fine cooking properties. Per packet, 4d.; per oz., 10d.

Barr's Champion Solid White Celery, solid and sweet, remaining long in condition. Per packet, 1/- and 2/6.

Barr's Paragon Cabbage Lettuce, light green, leaves smooth and succulent, medium size, all heart, sweet and tender. Per packet, 1/-; per oz., 2/6.

Barr's Scarlet Perfection Radish, an extra-fine, very early, short-topped, turnip-shaped Radish; colour, rich scarlet; flesh white, mild, and crisp. Per oz., 8d.

Barr's Early Ruby Tomato, solid, deep-red fruit of fine form and medium size, abundant cropper and very early. Per packet, 1/-.

BARR'S SEED GUIDE contains a Select List of the best Vegetables and the most beautiful Flowers for Garden and Greenhouse. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. Sent free on application.

BARR & SONS, 12 & 13, KING STREET, COVENT GARDEN, LONDON.
Nurseries: LONG DITTON, SURREY.

CALADIUMS.—Our Speciality for many years. All the finest sorts, extra strong bulbs for specimens. Catalogues post free. — **JOHN LAING & SONS**, The Nurseries, Forest Hill, S.E.

ALL WHO WISH GRAND RESULTS should use **THOMSON'S IMPROVED VINE, PLANT and VEGETABLE MANURE**. This valuable Manure is yearly growing in public favour. Can be had of all Nursery and Seedsmen, or direct from the makers, **WM. THOMSON and SONS, Ltd.**, Tweed Vineyard, Clovenfords, Galashiels, N.B. Price Lists and Testimonials on Application. 1 cwt. and upwards Carriage Paid to all stations in Britain and Ireland. London Agent—**Mr. J. GEORGE**, 14, Redgrave Road, Putney. Agent for Channel Islands—**Mr. J. H. PARSONS**, Market Place, Guernsey. Also **THOMSON'S SPECIAL CHRYSANTHEMUM MANURE**. 1/2 cwt. Carriage Paid to all Stations in Britain and Ireland.

FOR SALE, *Journal of Horticulture*, 1891 to 1899. Clean, in Nos. What offers? (17 vols.).—**E. C.**, 11, Saxevel Street, Derby.

HEATING APPARATUS for Greenhouses and other Buildings. Catalogue free of all kinds of Hot Water Pipes, Wrought and Cast Iron Boilers, Radiators, Cisterns, Pumps, Baths, &c.—**JONES & ATTWOOD**, Stourbridge.

THE GARDEN MANUAL, for the Cultivation and Operations required for the Kitchen Garden, Fruit Garden, Flower Garden, and Florists' Flowers. Illustrated with Engravings and Plans. By the Editors and Contributors of the *Journal of Horticulture*. REVISED EDITION now ready. Fcap. 8vo, cloth, price 1/6; post free, 1/9. ** 44,000 of previous editions already sold.—**OFFICE**, 12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent, each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—**HIRST, BROOKE & HIRST, Ltd.**, Leeds.

GREENHOUSES from £3 5/-; **VINERIES**, **CONSERVATORIES**, **FRAMES**, **SUMMER HOUSES**, &c. Illustrated List Free. Makers to **H.M. THE QUEEN** and **H.R.H. THE PRINCE OF WALES**.

E. B. HAWTHORN & CO., Ltd., London Works, READING. (Name Paper.)

No. 1026.—VOL. XL., THIRD SERIES.

ECKFORD'S SPECIALITIES

ONLY GENUINE DIRECT FROM WEM
AWARDED 46 GOLD & SILVER MEDALS

SWEET PEAS!

The **BIGGEST SUCCESS** of all is **ECKFORD'S GIANT SWEET PEAS**. The **PURITY** and **STAMINA** of these Home Grown Stocks are so conserved by **SPECIAL METHODS** of CULTURE that the seeds are **PHENOMENAL** for **UNRIVALLED STRENGTH** and **VITALITY**, and with proper cultivation, give the **HIGHEST POSSIBLE MAXIMA** of results! Prizes offered in 1900 alone exceed **£40!** Collections from 1/6 upwards.
(See particulars in Catalogue.)

See beautiful plate of **SWEET PEA NOVELTIES** for 1900, sent gratis with each Catalogue.

CULINARY PEAS!

ECKFORD'S CULINARY PEAS are positively **UNRIVALLED** by any on the Market for **FLAVOUR** and **CROPPING CAPACITY!** **ENORMOUS YIELDS** under favourable conditions. Collections for 5 months continuous supply (See page 2 Catalogue.)

PURE VEGETABLE SEEDS!

Results from **ALL QUARTERS** prove that **ECKFORD'S SEED**, for **PURITY**, **VIGOUR**, and **YIELD**, are the **CHEAPEST** and **BEST** ever offered to the Public! Collection for 12 months supply, **12/6, 21/-, 42/-, 63/-, 105/-**, all carriage paid. Other Collections, **2/9, 5/-, 7/6**, post free.

CINERARIA (SILVER MEDAL STRAIN). Giant Flowers, splendid habit, unequalled!
PRIMULA SINENSIS. Unique Novelties and Grand Collection of named varieties.
PANSY. World-famed strain of **FANCY, SHOW, PEACOCK**, and **FLAKED VARIETIES!**
VERBENA. RENOWNED RACE of EXCEPTIONAL MERIT!

Don't buy till you have seen it! **ILLUSTRATED Catalogue & Cultural Notes POST FREE!** If you love Gardening send for one!

By Special Appointment

ORCHIDS.—ORCHIDS.

QUANTITY IMMENSE.

to H.R.H. the Prince of Wales. Inspection of our New Range of Houses IS CORDIALLY INVITED BY
HUGH LOW & CO., BUSH HILL PARK, MIDDLESEX.

WEST'S PATENT GARDEN SPECIALITIES.

WEST'S PATENT Vapourising Fumigator

Best and Cheapest, for being made of brass and zinc will last for years. The stove only requires a little spirits to saturate the asbestos, so may be used thousands of times without wick or further trouble than filling it. Price 6d. complete to vaporise up to 2500 cubic ft.

"**WEST'S EXTRACT OF NICOTINE**" is guaranteed pure Nicotine and is even cheaper than the compounds that are only chemical substitutes for Nicotine (compare prices), 7d. per air-tight sealed bottle of 1000 cubic ft.

"**SUNPROOF SHADING** in 6d. lb. tins ready for use, to be mixed with cold water. Guaranteed to be perfect in all respects and the cheapest shading that can be made.

For particulars of West's patent "Ivorine" Plant Labels, Soft Metal Tree Fasteners, S.M. Clips, Wall Nails, Plant Stake Grips, Plant Pot Crocks, Insecticides, Fertilisers, Canes, Sticks, and **ALL GARDEN SUNDRIES** of every description see Illustrated Catalogue, post free.

Samples free, postage for samples and goods extra. All goods made on the premises by **C. E. West**, so send direct to the Manufacturers.

Gratis, "**Orchid Culture**," 3rd Edition, postage 2d. Gives full particulars of the cultivation of Orchids.

CHISWICK GARDENS.

No. 19 OF LONDON GARDENS OVER FIFTY YEARS.

MANY a gardener has passed through Hammer-smith having Chiswick for his destination, and wondered, perhaps, while on the road, how it was the gardens of the Royal Horticultural Society were located in that suburb. It is certain the gardens have a distinct historic connection with the mansion of the Devonshires, for it was mainly owing to the friendship between the possessor of Chiswick House in 1825, grandfather to the present Duke, and Joseph Paxton, that the Society acquired the ground which has been the scene of its practical operations for three-quarters of a century. Though Chiswick had in the past its noble and illustrious residents, it was best known as a fishing village. The special locality where the fishermen quartered mostly rejoiced in the unpleasing name of Slut's Hole. Chiswick itself, by its name, alludes to the sandy subsoil, as sand or gravel underlie a free loam, rendering drainage easy. Hence first farmers, and then market gardeners, were glad to obtain land about the district to grow fruit and vegetables.

Nearly half a century ago, when the enthusiasm of the first great international exhibition brought people to England from every land, thousands went along the beautiful avenue of Limes at Chiswick, intent on viewing the Society's gardens and those of Chiswick House, to which the Duke granted the public occasional access. The enormous increase of houses about Chiswick, many of them of an inferior class, has not rendered the air purer by any means, nor helped floriculture; also the gales and frosts of recent years have killed off some trees once much admired. Hence the visitor now will miss a good deal that delighted people in 1851, but yet he would have to acknowledge that the grounds bear comparison with any about the London suburbs attached to private residences. Before the practice had become common it was usual to line the shrubbery walks with Ivy, St. John's Wort, Stoncrop, and other plants, that gave less trouble than grass edges because they did not require mowing.

In the flower gardens the plan was adopted of

No. 2682.—VOL. CII., OLD SERIES.

elevating some of the larger beds to break the uniformity that arises from an extensive space being covered with flowers. For a long time it was usual to place in each bed flowers of one colour, but the modern method of variety was afterwards adopted; also an improvement was made in departing from the regular or geometrical plan of arranging the beds. Pansies and Liliaceous species were much in evidence, which showed a succession of blooms beside usual herbaceous plants. Visiting the great conservatory, 300 feet long, in 1877, a friend was astonished at the grand display of Camellias during May, while autumn was remarkable for the varieties of climbing Fuchsias, and, at all seasons a selection of fine-foliaged species made a show.

Concerning the trees and shrubs it may be noted that the Lebanon Cedar is very observable. Near Chiswick House are several ancient trees, beyond these an avenue of younger specimens, but the locality is not favourable for Conifers. Portugal Laurels are numerous, some particularly large ones have increased by layering, also a good space is occupied by Rhododendrons, most of them of fine growth. Probably nowhere near London are grown together as many examples of the Evergreen Oak, and the varieties of Holly are numerous, both scattered trees and others edging paths or avenues.

What is called the Napoleon Walk has a Yew hedge that is one of the glories of the place, it must be nearly 20 feet high. At one end of it is a fine Deodar, planted by the Emperor Nicholas in 1844. Another Yew hedge occupies one side of a walk, on the other of which is a ha-ha. This hedge has its sombreness relieved by recesses here and there, these affording space for Golden Yews. The Bay ground, which gives a pleasant view over the water, has been admired on account of its trees, which give the name. Amongst the remarkable single trees we notice an immense Oriental Plane, a large Hornbeam, which is rare, and an old May Duke Cherry.

It is manifestly impracticable to condense here any account of the history or progress of the Society's gardens during the fifty years. As a rule organisations move slowly, and are inclined to Conservatism, so that has made the changes fewer. Generally, we might say, what alterations have been made are improvements. Some things the Society did in the past it cannot repeat now; for instance, adding great accessions to our list of exotics. Previous to 1850 the lamented Douglas had sent to the Society upwards of 200 hardy species, mostly showy, amongst them *Ribes sanguineum* and *Nemophila insignis*. Important acquisitions from America were due to Hartweg, and from China to Fortune. At that date the experimental fruit garden had been for a quarter of a century under the management of Mr. Thompson, a man of keen insight, with great knowledge of the habits of trees, and the qualities of fruit varieties. The experimental departments for flowers and vegetables were always an object of special interest, but in these days many nurserymen have their own experimental gardens.

For a long time it is evident a large proportion both of nurserymen and private gardeners were ignorant of, or indifferent to, the benefits conferred on horticulture by the Royal Horticultural Society. A little before the date of which I have been writing, there was an instance of the Society's activity in behalf of agriculture and horticulture, in securing the aid of Prof. Solly, who undertook a research into the value of the different manures, delivering also a course of lectures upon the subject. The great conservatory was open to a good deal of criticism. Down the centre, where the plants were placed in a bed of soil, they grew so thickly at first that it looked like a bit of jungle, and the entrance was badly contrived, giving one the idea of a greater descent than there actually was. A peculiarity in the construction of this conservatory was the arrangement for ventilation, the air being led at the sides over gutters containing rain water, then across hot-water pipes, so that it might be both moist and warm. In 1850 or 1851 the Society exhibited one of the first houses built by Hartley & Co., showing the application of their patent rough glass. About the same time some new pits were made in the gardens, on a plan enabling the gardener to enter them without exposing the plants to rain or cold.

Some of the gardens and orchards at Chiswick used to be divided from each other by fine Hawthorn hedges, over which the wild

Convolvulus and Nightshade threw their sprays: none of the flimsy affairs called hedges that we see being planted now. The grounds were very neatly kept by Cook, Jessop, Mills, Dancer and others; the orchards of the last often presented a beautiful sight in spring; during a favourable season the Apples and Plums would be so loaded as to need the support of props. It is, however, one of the disadvantages of Chiswick that cold air, at times, descends into it from the uplands, causing mischief during winter or spring. The oldest nursery was that of Gleudinning on Turnham Green. It was probably started early in this century, when Heaths, and allied species now common, were novelties. It ceased to exist some years ago, the last occupier being Mr. Ewen. Twenty years ago a nurseryman in a small way occupied Hogarth House and its gardens. The place is supposed to have been favoured with visits from that illustrious painter, but time has dislodged this tenant too.

Before the vast increase of buildings about West London from the valley at Chiswick we could see clearly the heights of Notting Hill, Bayswater, and other localities towards Hyde Park. Bayswater, though not on the river like Chiswick, yet bears a watery name. It once had several springs and rivulets, and it is under the disadvantage, from the gardener's point of view, of being somewhat exposed to cold winds. The nurserymen formerly here have departed, but horticulture is represented in its squares and parlour conservatories or gardens of the residents in Westburnia, so called. Westbourne Place had, we read, beautiful grounds in the reign of George III., the owner, Jukes Coulson, employing some very skilled gardeners. He had as a neighbour the singular half crazy quack, Sir John Hill, who had a nursery where he cultivated plants for his decoctions and distilled compounds. Some people believed in his essence of Waterdock and balsam of honey. Subsequently his ground was turned into a public tea garden.

On Craven Hill, which had belonged to Lord Craven, was the nursery of Messrs. Hopgood, which flourished some years there. About 1845 the firm removed to Shepherd's Bush; the place was closed a few years ago. The later years of the life of the illustrious J. P. Loudon were passed in a Bayswater mansion called The Hermitage, where, after he was unable to employ himself in landscape gardening, he made experiments in the construction of houses. Not far from him resided Count de Vandt, a great admirer of Roses and a collector of showy exotics. Mr. Burley's nursery of Hereford Road, now vanished, attracted visitors in 1877 to see his specimens of *Aspidistra punctata*, a remarkable plant very little known then. Its flowers, which are purplish in colour, are matured under the soil, seldom coming into the daylight.—J. R. S. C.

SEAKALE FROM SEED.

THAT good roots of Seakale, suitable for forcing, may be had the first year from seed, was fully demonstrated by Mr. Atkins at the last meeting of the Kingston Gardeners' Mutual Improvement Society. The lecturer dealt with the system of growing and forcing in beds, but his principal point was the management of seedlings to produce a crop of Seakale for the kitchen the first year. To do this, choose an open site for the seed bed, and it is very material that the ground be trenched, or bastard trenched, and well manured. Not later than the end of March sow seeds at 6-inch intervals in drills 18 inches apart, keeping the bed clear of weeds and the surface loose with the hoe. A dressing of salt, 4 lbs. to the rod, or sprinklings of nitrate of soda just before rain, will be of great benefit to the seeds and young plants.

In December lift all the crowns, taking extreme care to secure all the roots. In the absence of a Mushroom house put the roots in 12-inch pots in fairly good soil, and cover each pot with another, inverted, and place them in a temperature of 50° to 60°, the former for preference. It is not wise to attempt to force these yearlings too early or too fast, for that would be courting failure, but for producing heads from the end of January onwards such roots are excellent. Mr. Atkins exhibited, as illustrative of the practice, a dozen roots with heads ready for cutting, which were very good indeed, and as Mark Twain pertinently says, "Never agin a success."

The variety recommended for this system was the old Purple, as this seems less liable to disease than the newer Lily White, at least on some soils. No remedy for the disease was given by the essayist, neither could the audience give one. Seakale was recommended as a crop which cottagers would do well to grow. A rod of ground will produce about 160 crowns, which means many dishes of this delicious vegetable. It was stated that several cottagers round Cambridge cultivate Seakale either from seeds or by the ordinary method of cuttings, and often pay the year's rent with the proceeds, besides securing an occasional dish for their selves.

Mr. Atkins, it is interesting to note, practises on Kingston Hill,

which is well known for its shallow gravelly soil, and where it is difficult to grow anything in dry seasons. This, therefore, makes his experiments with Seakale all the more valuable, and, in my opinion, is conclusive evidence of the excellence of the system he so ably advocated.—J. T. BLENCOWE.

ODONTOGLOSSUM CRISPUM MUNDYANUM.

There were very few Orchids at the meeting of the Royal Horticultural Society held in the Drill Hall on Tuesday, February 13th. The weather was against growers bringing out their plants. As a consequence the Orchid Committee gave few honours. One recognition took the form of a first-class certificate to N. C. Cookson, Esq., Wylam-on-Tyne, for *Odontoglossum crispum Mundymanum*, which is portrayed in fig. 38. It is a strikingly beautiful variety, with flowers of good form and size. The ground colour is white with, as may readily be seen, immense markings of reddish chocolate. The margins of the broad sepals and petals are slightly serrated. The splendid lip is white with prominent red markings. It is a variety of the first quality, and was much appreciated by visitors to the Hall, as was *O. c. Cooksonianum* from the same source.

EPIDENDRUM (DIACRIUM) BICORNUTUM.

AMONGST the several Orchids that give the majority of growers a considerable amount of worry and anxiety must be classed *Epidendrum bicornutum*. These troubles result from, in some cases, an inability to flower the plant at all, and in others from the fact that the stock gradually dwindles after perhaps flowering once until it has to be thrown away. This failure I consider to be extremely regrettable, as the flowers, when the plants are well grown and can be kept in good health, are amongst the most attractive in the entire Orchid world. They possess an exquisite beauty that appeals to everyone, and every season one appears better and better able to appreciate its peculiar charms. The flowers of *E. bicornutum* (fig. 39) have not the gorgeous colouring or the size of the *Cattleyas*; but they have a grace that is entirely their own, and which renders the plants worthy of more than extra care on the part of the grower.

It is now many years since the culture of this Orchid was first taken up at Sunningdale, and I need scarcely say I entered on the task in some fear and trepidation, as was natural considering the reputation the plant had made for itself. I was, however, determined to succeed if such a thing were possible, and I may say, without being accused of egotism, that I have done so. On more than one occasion the exhibits that have found their way from Sunningdale Park to the London shows have been eulogised in the pages of the *Journal of Horticulture* and its contemporaries, which will be sufficient warrant for the task I am now undertaking. This is to give briefly the methods that have been adopted with the plant, and which have resulted in regular flowering, and what is perhaps more important, constant improvement in the condition of the stock.

At the outset the difficulty was to find the best place for the plants, and it was only after repeated trials that they eventually reached a hip-roofed Pine stove. They were suspended over the path, and after a time it was plain to see that the position practically met their requirements. However, they were destined to undergo another move, for Pine growing was discontinued, and I cast about for a new and equally good position. This was found in the structure they now occupy, which is a span-roofed Croton house, running east and west, and fitted with lath roller blinds. This place was chosen because previous experience had taught me that the plants must have almost all the light that our climate affords; and as it is only under those conditions that we can insure the highest degree of colouration in the *Crotons* this appeared to be the place. The results have far exceeded my most sanguine expectations, for, as many expect Orchid growers can testify, the plants simply luxuriate.

Thus the vast majority of gardeners can supply the chief requirement without much trouble, as they have only to choose between the Pine stove and the Croton house. The next step must be the basketing of the plants. I prefer for this purpose shallow teakwood receptacles, as it has been proved that the plants like to dry rather quickly after watering, which would not occur if deep baskets holding a considerable quantity of compost were employed. "But," will be asked, "what shall the compost consist of?" and I would reply about 2 inches of the best peat and broken crocks, with live sphagnum moss over the drainage. This does not sound much, but as a matter of fact it will be ample for our purpose. For potting or renewing the

compost we choose the period immediately after the plants have ceased to flower, after which the only attention they receive or require is watering, but this must be done with care and judgment. Thrips should not attack the plants, but if they do the structure must be fumigated.

During the winter months the plants are suspended on the south side of the house, but in the summer they occupy the northern slope. As has been said, they must have ample light, and the lath blinds are only run down in the summer when the sun is shining very fiercely, and they are drawn up again very early in the afternoon. The house is always closed with plenty of moisture, but never to the point of stagnation. As a matter of fact, it is to the atmospheric conditions that I attribute my success with this and other "miffy" Orchids. The atmosphere, I insist, must be kept sweet, no matter how moist and warm it may be. There must be an absence of that stuffiness which is common to some houses, as such a state will inevitably lead to failure. I like the house to feel comfortable to all who may enter, and not to be close and oppressive. I should have said previously that the compost must never become sodden; indeed, the roots are better just on the dry side during the short days of winter.

These directions are very simple, but they are exactly such as I have long adopted, and which I am convinced will lead anyone to success if they are carefully observed. If I have omitted any point

FIG. 38.—ODONTOGLOSSUM CRISPUM MUNDYANUM.

that a reader desires information upon, I shall be glad to give it, as my great desire is to see this Orchid as extensively grown as its merits entitle it to be. I may add that *Broughtonia sanguinea* will flourish under similar conditions, but requires slightly less peat and sphagnum moss.—F. J. THORNE, Sunningdale Park, Berks.

CYCLAMEN CULTURE.

It is difficult to say why, but the fact remains that many excellent growers of plants still consider the growing of a good collection of *Cyclamens* a test of superior ability. That they require care, I admit, but they are certainly as easy to grow as *Pelargoniums*. And to go even further than this, I think I can say that to present *Pelargoniums* of the regal section in the form our best exhibitors do is a much more difficult task than to do the same with *Cyclamens*.

It is a pity that private growers—where possible—do not study more closely the way the market men grow their plants. They would often learn useful lessons that would save them much unpleasantness and disappointment. And one of the things they would learn would be that the majority of the plants they grow are too much coddled and kept too warm summer and winter. The *Cyclamen* is an instance of this. In reality a semi-hardy perennial, it is treated in many instances like a tropical or stove plant, with the result that much of its natural vigour is lost.

First the seeds are sown in a strong bottom heat; when the seedlings appear they are kept from every breath of air, and usually spend the first six months or so of their lives in a Melon house on

the shelves, or in an overheated plant stove with other occupants equally ill-treated and debilitated. I am not saying this is the case in all private gardens, but that it is in many I have had ample evidence for many years.

Again, the practice of keeping the old corms year after year and subjecting them in summer to a kind of roasting and drying system under the impression that some great good is being done, has nothing to recommend it, but it is one of the old customs that die hard. Twelve or thirteen years ago I was growing these plants for market, and staged a dozen at a West of England Show only a little over a year old but crowded with fine foliage and flowers. This system was not then so widely known as now, but even yet it is not practised as much as it ought to be.

Cyclamen seeds should be sown during October and November or in January according as they are wanted in flower early or late, and for a succession seeds may be sown at all three months. I like to dibble the seeds in separately, about half an inch deep and an inch apart. Cover with a little clean moss and stand the pans in a warm moist house. This allows of their remaining without disturbance until the seed leaf is well developed. I used to leave them longer, but I am convinced that it is a mistake to leave them until the next leaves are strong, as the roots become more matted, and it is difficult to remove them without injury.

An ordinary greenhouse temperature now answers well, but the dry parching atmosphere found in some greenhouses suits them very badly, and they would be better in heat than in this. What the plants want is ample light and a genial growing temperature; they may stand pot thick, if necessary, so will not occupy much room until the leaves begin to push up, when each one must stand well clear of its neighbour. But while liking ample light, due protection from the midsummer sun is necessary, and this is best provided by movable blinds of light, thin texture, and which must only be used when necessary.

The plants may go into their flowering pots in September or earlier if they are ready, and must never be shut up in a close, hot, and moist atmosphere. As to the depth to place the corms when potting, let them just peep cut of the compost, and the sinking of the soil and the growth will place them exactly right just out of the soil.—H. RICHARDS.

NOTES FROM IRELAND.

THE WEATHER.

The weather for the past week has certainly tested the resisting qualities of everyone. In many places the intense cold has damaged stove plants, whilst Cinerarias have also suffered. The following particulars have been issued by Mr. F. W. Moore, Curator of the Royal Botanic Gardens, Glasnevin:—"It may interest your readers to know that on Saturday night last the minimum thermometer on the grass (a registered and certified instrument) registered 22° of frost, falling to 10° Fahrenheit. This was the coldest night registered here since 15th of December, 1882, when there were 22·4° of frost. On the 24th December, 1878, there were 27·4° of frost. Fortunately, the snow has given place to a few showers, which have done dual duty by removing the snow, and at the same time removing it with the greatest safety to vegetation. The weather at present is good."

AN ACCIDENT.

A rather sudden fatality occurred recently amongst the rank and file of gardeners in the death of Mr. James English, the trusted gardener-in-chief to the Oblate Fathers at Inchicore, Dublin. It appears Mr. English was engaged in pruning, he having placed a ladder against the tree, and whilst severing some of the branches, lost his balance, and received severe bodily injuries. He was conveyed to the hospital, but the skilled attendance was ineffectual to prolong life. The deceased leaves a wife and family to mourn his loss, and in return for his valued services the Oblate Fathers have made arrangements that his family shall not need the support accorded by the city.

A NEW NARCISSUS.

I have recently visited the well-appointed gardens of Mrs. Black, Blackheath, Clontarf, and the skilled and unassuming gardener, Mr. Hume, escorted me to a row of hybrid Trumpet Narcissus. There was a fair number of flowers in all stages of development, but owing to the frosty weather the perianth segments were partially closed. It is a new seedling that has been in bloom since the first week in January, and has received no protection. The blooms are very fine, and this variety is destined to have a great popularity, owing to its earliness and the size of the bloom. The flowers enclosed in the tin box are those alluded to above. They were barely open, and I trust will be received in good condition.—A. O'NEILL.

[The Narcissus sent are certainly of great promise, but it is hardly fair to judge of the size and colour of the flowers, considering the weather to which they have been subjected. Perhaps Mr. Hume will send us a few more specimens a little later?]

PINCHING FRUIT TREES.

UNDER the head of "Blossom Bud Formation," on page 137, "S. S." desires to know "at what months of the year shoot pinching must be done, and the manner of doing it, to produce similar effects to root pruning?"

In the first place, let me say that if "S. S." means by the term "similar," effects which are "exactly the same," as I know some casual readers do, and as the quotation rather implies, it is necessary to point out that I very clearly stated, on page 87, that while the arrestation of growth by shoot pinching facilitates the formation of fruit buds, I was careful to add, "a more marked, quicker, and greater increase of such buds can be brought about by the still greater growth arrestation effected by checking the extension of the roots." Let there be no misunderstanding on this point, no confusion of terms which may be similar, but far from being precisely the same. It is easy enough to write, but not always easy to make everybody understand exactly what a writer seeks to convey.

I now fear I must disappoint "S. S." No person living can tell him exactly when and how to pinch his own trees to induce them to form blossom buds, at least without seeing the trees, and even then they may be in such a state of weakness on the one hand, or strength on the other, as to be beyond being usefully influenced by the process in question. There are thousands of such trees almost all over the country, but also thousands more that could be made to bristle with blossom buds as the result of pinching the growths in the right manner and at the proper time.

Ancient Pear trees, for instance, against walls, or trees that for a generation have produced weak summer growths from among the worn out and attenuated spurs on the lower parts, and stronger growths on the upper portions, such growths having been allowed to extend through the summer to be cleared off in the autumn or winter; trees of that kind cannot be made satisfactorily fruitful by summer pinching. The time has long gone by for that to be effected.

The same can be said in respect to bush fruit trees of any kind in the open—Apples, Pears, Plums, Cherries, Red or White Currants, and Gooseberries. If any of these have been permitted, as countless numbers are, to produce something like a thicket of long summer shoots to be cleared out in a wholesale way in the winter, and the practice has been resorted to for some years, it would be futile to expect that they would respond by shoals of blossom buds to summer pinching. They will do nothing of the kind. A few might be produced, no doubt, by a scientific gardener such as Mr. Abbey, or an equally competent amateur in fruit culture like Mr. Ellison; but a venture may be made in saying that neither of them would rely on the practice, as they must both know, to use an expressive simile, that the "game would not be worth the candle." No, they would resort to different means; and why? Because it would be too late to render such trees fruitful by pinching alone.

Such cultivators as those named know very well what all who are engaged in fruit culture should clearly and fully comprehend, that all those summer shoots made and cut away annually, and in aggregate length enormous, have each year been engaged in producing in the soil roots of corresponding length and strength; and, as these roots are in their substance perennial, their accumulated force becomes so great that it cannot be subdued by shoot pinching, summer pruning, or any kind of pruning that involves the shortening of branches, to the extent of materially inducing blossom bud formation. It would not be difficult to explain the manner in which such trees should be treated, but that is not the question at present.

The cardinal point to remember is this—when the underground branches of a tree become much more powerful than the leaf branches, as must of necessity be the case when long, strong growths are produced in summer and cut closely out in winter, practically all the buds retained are forced into further growths essentially of a blossomless character. If we go to the other extreme and find the roots proportionately much weaker than the branches, then many or most of the wood buds will change to blossom buds, and the tree make little, perhaps too little, growth. We want the mean between the two extremes—a due balance or equilibrium between the part of the tree within the ground and the part above it. There will then be neither an undue preponderance of growth nor blossom, and the tree will be fruitful yet healthy. Young trees can be moulded into this condition by pinching the summer side growths before they become strong, as by arresting their extension, the extension of the roots is also at the same time checked; and partially, if not mainly, as a consequence of this, and partly as improving the basal leaves as organs of sap elaboration and assimilation, blossom buds certainly form, simply because they cannot help it. The apical extension of the normal buds is arrested, and the embryonic leaves within them are changed into petals and organs of fructification.

When shall we pinch? Not, in my opinion, as Mr. Mitchell said last week (page 137), until we form the trees—i.e., obtain sufficient main branches by shortening the few first produced. Some persons shorten the growths more or less severely because there are too many of them, as if there would be fewer another year! There will be more. Shortening the growths increases the number. We must winter shorten till we secure the requisite number, then stop the process, for an excess of main branches is injurious, as being antagonistic to fruitfulness. Most trees and bushes have far too many main branches. Those of the larger-leaved kinds are better, on the average, 18 inches than a foot apart, this latter distance serving for bush fruits.

From the main branches thus formed and disposed side growths issue. These are frequently too numerous, and in such case the removal of some when an inch long, or before, is excellent practice—disbudding. Now assuming all that form are allowed to grow till the autumn, and the main branches are at the same time much too close together. What is the result? It can only be a bundle of crowded shoots and leaves—a thicket. In this case, which is much too common, what is the condition of the basal leaves of these shoots? Sap is drawn from them by the stronger parts above, while the vitalising influence of the sun is denied them. These lower leaves are then of necessity structurally and chemically weak. They cannot, or only in the slightest degree, discharge their respiratory functions, which is the first necessity for the manufacture of starch from carbon obtained from the air and materials supplied by the roots. In other words, they cannot provide and store organised matter in the stems adjacent to where the blossom buds should be. The resources of the soil and air are secured and used by the better leaves above them, and these very parts are cut away in pruning and burned. What short-sighted practice it is?

Let us look at the more rational way. This is easy, economical, and effectual. Prevent the elongation and crowding by pinching the shoots. As to the "time" this should be done, it may be said that it cannot all be properly done at any one time; nor at the same time everywhere. It depends on the growth of the trees. The shoots first elongate from the upper parts of the branches of bush trees, and also along the parts of those near the tops of walls. These strong shoots are usually ready for pinching by the middle of June. Nip or snap off the tips above the third or fourth full sized leaves, not counting the small basal leaves. The knife ought not to be required. The sap is then diverted into the lower and weaker shoots, and strengthens them for pinching a week or so later, and soon afterwards the process should follow with the weakest series at the base. By this simple and rational division the strength of the majority becomes equalised.

By this early pinching it may be feared by some persons that the back buds will start into growth. Only the two top ones will do so, rarely three, while the buds in the axils of the small basal leaves will be strengthened. When the two secondary growths unfold two or three leaves pinch them to one, and if tertiary shoots or sub-laterals follow treat them in the same way, allowing one leaf to remain in each instance. The effects of this discriminate pinching are manifold. 1, By topping the longer first, and the weaker shoots later, these are strengthened. 2, By preventing the elongation of hundreds of growths and the development of thousands of leaves, the elongation of what would be correspondingly long and strong roots is to a material degree checked. 3, The mineral constituents of the soil are economised instead of being spent on shoots to be burnt. 4, If the soil be firm, yet porous, as it ought to be, not very rich and not thoughtlessly dug, fibrous roots will be incited. 5, The basal leaves on which the sap is concentrated, and the sun can shine on them, become ten times better than under the smothering system, and ten times more nutrient matter is stored in the portions of wood that are not cut off; and, 6, the general arrestation of roots so modifies the sap pressure that all the basal buds are not forced into leaf and wood growth, but a sufficient number are changed into floral organs, fruit following it if weather permit. It is easy to assist Nature to change wood buds into blossom buds, but difficult to thwart her laws by changing fully developed blossom buds into wood buds—at least I have not been able to accomplish the feat.

Some readers may not unnaturally think that all the pinching described involves a good deal of trouble, and they may ask if I would do it myself? As to the trouble it is not so great as it seems, and I have applied the process to garden trees that had to be kept within narrow limits, and yet to be laden with blossom in their season. With unlimited space, and for utilitarian purposes I should adopt a different method. If the branches of fruit trees are 2 feet asunder, and the side growths only of moderate strength, the sun can reach the basal leaves which become stout and strong, quite sufficient blossom buds forming for a crop of fruit as heavy as the trees can profitably bear. This, as in the case of the pinching, is the teaching of experience.—A LINCOLNSHIRE GARDENER.

SWEET PEAS.

THE BEST WHITE.

I AM often asked which is the best white Sweet Pea in cultivation. For years I invariably replied Emily Henderson, but at last I must change my opinion. Not that this variety has deteriorated in any way, but simply because a better has found its way into commerce. Mrs. Sankey was thought by some persons to be the best white, but any variety that is distinctly tinted with pink cannot well lay claim to the title. Eckford's Sadie Burpee is now my favourite. The blossoms are of such splendid substance, while their purity is undisputed. This is what is known as a hooded variety, which means that both standard and wings incline inward at the edge.

CREAM OF BROCKHAMPTON.

Anything new in what are termed yellow Sweet Peas is sure to be welcomed. Not that I think any variety has a right to the name of

FIG. 39.—EPIDENDRUM BICORNUTUM.

yellow as yet, for no one can say that we have a true yellow-flowered variety. In Cream of Brockhampton we have the nearest approach to that colour. The standards contain more cream colour than do those of Mrs. Eckford, which hitherto has been regarded as the best variety of that tint. The new comer is one of Mr. Foster's seedlings.

GORGEOUS.

I should like to supplement what "Practice" says on page 99, about this Pea. The colour is quite unique, and thoroughly deserves its name. On reference to my notes of new varieties last year, my colour description is much more elaborate than that given by "Practice;" it contained so much variety of colour that I noted it carefully. This may not, however, be correct for all that, as the descriptive tints of colour are very much a matter of taste. Here it is a standard orange red suffused with apricot, wings pale rose with a purple suffusion, keel pale lilac. A grand flower in every way, and quite one of the best of Burpee's introductions.—E. MOLYNEUX.

A NATIONAL FRUIT SCHOOL.

"A NOTTS GROWER" should not too hastily assume that the establishment of a national school of horticultural practice, such as I referred to recently, is so much of a chimera. It is evident that Sir Trevor Lawrence, the President of the R.H.S., does not think so either, for in the brief reference he made to the hoped for new Chiswick, though his mouth being yet closed as to details because of negotiations in progress, he seemed to think that the Society, with the aid of a combination of numerous County Councils, would in time create this desired school.

It is unfortunate that a proposal so fraught with interest to horticulture should be put forward at a time when the nation at large seems to be most concerned with watering South Africa with human blood: but there are some persons at least who can look forward with hopefulness to what must be regarded as a desirable consummation.

When I referred to the need of a school for practice in fruit culture, of some 200 acres in extent, I wished it to be understood that it was desirable to train students practically, under such conditions as they would later find in any considerable fruit farm, such as they might be called upon to manage. No school of limited area could furnish the experience that a large area could provide, because in the latter case there would be ample scope for general culture of all descriptions of marketable fruits, as also for such experimental work as it may be desirable to conduct. A national school of horticulture, to have any prominent status, should have 100 pupils at least, and if with the aid of County Councils the R.H.S. can eventually supply such a school, then will its inauguration be a red letter day for British horticulture.—A. D.

CRYPTOMERIA JAPONICA.

REFERRING to the note by "C." (page 88) on this Conifer, I must say that I have been much disappointed with it after it attains a height of 12 feet. From that time it becomes unsightly, losing its feather, as it were, on the inner growths to such an extent that it presents a mass of dead branches. So ragged and unsightly have scores of plants of it become, that they have all to be cut down and burnt as they approach that height. Up to 6 feet high it is excellent for the garden in winter, when its bronzy red hue is so pleasing.

Plants from 6 inches to 4 feet high are largely employed for filling the flower beds during the winter months. No Conifer that I know stands the twice planting that stock for this purpose have to undergo during the months of May and October so well. This is mainly owing to the mass of fibrous roots annually produced. *C. japonica* is easily propagated by half-ripened shoots of the current season's growth taken off about 6 inches long early in September and dibbled firmly in a sandy soil in a cold frame. These make capital plants in two years' time, and are well suited for edgings to beds of other shrubs for a season or two. They can afterwards be employed in other parts of the beds with advantage. The soil here varies considerably. Naturally it is heavy and retentive of moisture, in many places it is lighter, so much of an artificial character has been added of late years; still the results are the same.—E. MOLYNEUX.

THE ROYAL HORTICULTURAL SOCIETY'S ANNUAL REPORT.

If the issue of the report to the Fellows a fortnight before the date of the annual meeting necessarily detracted from the freshness of the document when the meeting took place, at least it furnished ample opportunity for perusal and comment, matters of undoubted advantage. In making a few comments on the report I would first correct what seems, as I have been informed, a printer's error in connection with the name of that esteemed young gardener, Mr. W. H. Lees, which has been inserted in the Fruit Committee list, but should be in the Floral Committee list.

Then I observe that the report in a very unobtrusive way makes public a fact of some interest that was not referred to when the list of the Council was published in the ensuing year's "Arrangements," issued just previously. It is that the President, Sir Trevor Lawrence, having overcome the modesty which characterised the whole of the Council in 1897, has accepted the V.M.H. which fell in as vacant by the death of the late Mr. T. F. Rivers. This matter is not mentioned in the report, but is found only in the blue fly leaf issued with it that refers to the election of officers. Naturally the original objection on the part of members of the Council to accepting their own honour could not continue to exist when already two of the original holders of that initial affix are practically members of the Council.

This very blue fly leaf referred to made the welcome announcement that the farce of issuing balloting papers at the general meeting, collecting them, and appointing scrutineers to count and report on what was a foregone conclusion, is now abolished. Under the provision of the new Charter which has been granted there are common sense rules, and where there is no contest there is no ballot. We see also another excellent feature in the new Charter is that members retiring may be again and at once re-elected. As a result we see that that most estimable and kindly amateur gardener, Sir J. T. D.

Llewelyn, M.P., again rejoins the Council, and he will be supported by Mr. F. Du Cane Godman, whom I do not know, and by Mr. Arthur Sutton, whom everybody knows, and who should be able to bring to the Council some very valuable business knowledge.

I looked with special interest for that paragraph in several previous reports, in relation to the Committee awards at the meetings and shows, that had become apparently stereotyped, but was glad to find that it had been withdrawn. Seeing that the Council had so materially increased last year the number of the meetings, a certain increase in the number of the awards during the year became inevitable. The total number of awards for 1898 was 906, and for 1899 931. In the present list we find the Temple and Crystal Palace Show awards set out in separate columns, as are the awards at the Hybrid Conference, and probably this arrangement accounts to some extent for the apparent reduction of the Floral Committee awards from 432 in 1898 to 317 last year. The Orchid Committee, however, have been rather free with awards, having bestowed no less than 216 last year, as against 193 the preceding year, and of this 216 no less than 84 are awards of merit, as against 124 from the Floral Committee for all other flowers, and only 47 from the Fruit Committee for fruits and vegetables. Evidently the Orchid gentlemen are very free-handed, if not too discriminating.

The Council made a very urgent appeal for assistance to enable them to continue the great Fruit Show at the Crystal Palace. Why the Palace directors should reduce their usual contribution to the Show fund by £50 is difficult to understand. It may be due to meanness, or it may be to the fact that the Fruit Show does not pay them. If the latter be so, doubtless the small attendance on the part of the public is due either to the distance the Palace is from London, or to indifference to the fruit as exhibited on the part of the public, or because the Show falls at a comparatively dull time of the year when public interest in such events is somewhat exhausted. Still all those who remember the marvellous interest shown in the great Guildhall exhibition, which, however, was free, must admit that the people of London did evince some interest in fruit then.

Turning to the Council's balance-sheet for the past year, I found the Crystal Palace Fruit Show credited with a cost of £302 1s. 5d.—the pence show the Council's exactness—and with an income of £325 18s. That was very satisfactory, but of course includes the £100 raised by subscription to the Show fund and the £50 proposed to be withdrawn from the Palace contribution; but when I turn to the Temple Show account I find that whilst the cost of that great function was £686 14s. 10d., the income reached £1421 6s. 6d., showing a profit of considerably over £700. No doubt the Council like to make each show pay for itself; but this does seem to be a case in which what is, after all, a great society function may be expected to help pay a little towards the cost of such an eminently practical and valuable exhibition as the great Crystal Palace Fruit Show.

This fact is all the more emphasised when we found that the Hybrid Conference at Chiswick cost £211 13s. 11d., although that sum probably included the luncheon to the members of the Committees and visitors to the Conference; whilst the credit side showed only £56 14s. However, so far as the general financial position of the Society is concerned; and apart from the great increase in the number of Fellows, the Council have been able to carry over the huge sum of £1751 8s. 9d. as a balance to the general revenue account.—OBSERVER.

THE SEASON'S BLOOM.

I AM afraid if "A. D." had looked round our place with me about the time he was penning the notes on page 135, he would have written them rather sadly, provided he could sympathise with those who, like myself, will be called upon to supply a large establishment with fruit in a few months' time. I have never seen the buds so destroyed by birds as during the past two or three weeks. On all stone and also small fruits there is scarcely a bud left, and the snow was quite covered with the husk or shell of the buds cast by the depredators—sparrows and bullfinches. Last season, owing to the dry weather, the birds quickly ate or spoiled all fruits that were not netted. Sacks of good Apples were spoiled on large trees, but I think it worse to destroy the buds now and almost kill the trees.—N. KNELLER, *Malshanger*.

EPPING FOREST.—The Epping Forest Committee of the Corporation, in recommending that £4000 should be placed to the credit of the fund for the year ensuing, report that the thinning operations, which have been continued for nearly twenty years, have resulted in a marked improvement to the timber and undergrowth, while the natural growth of young trees, the timber of the future, has been promoted. The most urgent arrears have now been overtaken, and a much smaller annual felling has been necessary during the last and present seasons. Very little planting has been needed except for the purpose of hiding fences or other unsightly enclosures abutting on the forest and replacing trees destroyed by the drought. In this connection the Committee report that a very large number of fires occurred last summer in various parts of the forest owing to the extraordinary heat and drought, but in most cases the outbreaks were speedily extinguished, and, with one exception, no serious damage was done.

Recent Weather in London.—A considerable amount of rain has fallen in London during the past few days, as heavy showers have been of frequent occurrence. On Sunday afternoon it was dry and pleasant, but after that there was no permanent clearance until Tuesday night. It then turned colder, and on Wednesday morning at the time of going to press it was bright and frosty.

Weather in the North.—The frost became gradually less severe from the 11th to the 14th, when 12° were registered. A partial thaw set in on the 15th, followed in the afternoon and evening by a violent gale and snowstorm from the S.E. Roads and railways were that night blocked in various parts of the country. Much damage has been done to trees by the weight of the damp snow. Since Friday to Monday an imperfect thaw has been going on, but much snow still lies, even on the low grounds.—B. D., *S. Perthshire*.

Kidderminster and District Horticultural Society.—This Society held its monthly meeting on February 14th last. Mr. A. B. Whitehouse gave a lecture, illustrated with limelight views, upon the "Fertilisation and Hybridisation of Flowers." The lecturer explained some of the wonderful methods of Nature for the reproduction of species, and the methods employed for raising new varieties also examples of wind and insect fertilisation. Mr. Whitehouse was accorded a hearty vote of thanks, one member especially remarking that the fertilisation of the Fig had always been a mystery to him. Mr. Whitehouse kindly offered his assistance at any time, either by letter or appointment, to any member requiring information upon the subject of his lecture, an offer which was keenly appreciated by the members. This Society is now issuing its schedule of prizes for the flower show to be held on August 7th next, copies of which may be obtained from the Hon. Secs., Messrs. Rogers and Whacker, Brookfield, Blakebrook, Kidderminster.—F. W.

Salvia splendens grandiflora.—At one time the well-known *Salvia splendens* was in demand as a winter-flowering plant, and few good gardeners were without a supply of it, its bright scarlet flowers showing out prominently in the dull months of the year. Other varieties came, but the general public has not taken too kindly to them. But the advent of *Salvia splendens grandiflora* has altered opinions, and the old type will soon be looked upon as a thing of the past, as neither for profusion of flower nor habit will it for a moment stand against *grandiflora*, with its brilliant scarlet flowers. The habit is dwarfer and more compact. Cuttings taken now can be grown in sandy soil in a steady temperature, potted singly when rooted. When danger of frost is over the plants may be stood outdoors, and treated exactly as a *Chrysanthemum*. It is not wise to leave the plants too long outdoors in the autumn, the second week in September being quite late enough. If given a little warmth the plants readily respond, and furnish scarlet flowers in abundance for all kinds of decoration.—R. P. R.

Hessle Gardeners' Society.—This Society held its fortnightly meeting in the parish schoolroom. Mr. J. Stow delivered a lecture on "Coal and Its Relation to the Vegetable World." There was a good attendance, over which Mr. Mason presided. The lecturer, who was heartily welcomed by the members, asked them to carry their minds back to an age when the world was not inhabited, to a time when one lot of vegetation grew upon the graves of its predecessors. That vegetation was covered by water and other deposits, and pressed until at the present time they have that great steam producer coal. As an instance of how much pressure the vegetable matters must have been subjected to, the lecturer pointed out that the peat bed now at Thorne, which was 9 feet thick, if converted into coal would only produce a seam of a few inches. He also dwelt on the bye products of coal, such as tar, aniline, carbolic acid, and saccharine, specimens of which he produced. Mr. Stow also showed samples of various coal from different mining districts, in some of which impressions of Ferns were to be seen. Votes of thanks to the essayist and Chairman terminated a thoroughly interesting evening.—J. F. D., *Yorks*.

Floods in the Thames Valley.—We learn from a Maidenhead correspondent that during Saturday night there was a rise in the Thames in that district of over a foot, and on Sunday morning hundreds of acres of land in the neighbourhood of the river were submerged, and several riverside residences and hotels were flooded.

Royal Horticultural Society.—The next Fruit and Flower Show of the Royal Horticultural Society will be held on Tuesday, February 27th, in the Drill Hall, James Street, Westminster, 1 to 4 P.M. A lecture on "Some of the Plants Exhibited" will be given at three o'clock, by Rev. Prof. G. Henslow, M.A., V.M.H.

Birmingham Gardeners' Association.—The annual tea and social entertainment took place on the 14th inst. at the Colonnade Hotel, presided over as usual by Mr. W. B. Latham. There was an average attendance of members and lady friends, notwithstanding the unpropitious weather, and an excellent programme of music and song rendered the evening thoroughly enjoyable. The toast of "The Association" was appropriately rendered by Mr. Robert Sydenham.

Todeas.—Though Todeas are not numerous, there are a few whose characteristics stand out conspicuously, notably *superba*, whose graceful fronds are always admired. To produce the best results one only requires to follow a similar line of treatment as for *Trichomanes radicans*, popularly known as the Killarney Fern—namely, a dark place with plenty of moisture. In the gardens of George Rinahan, Esq., Roebuck Park, Dundrum, Dublin, are some exceptionally fine plants; the fernery is not very dark, but the light is much subdued. Unlike the Killarney Fern Todeas can be cultivated where light has an ingress, but instead of the delicate softness of frond, one gets a much hardier and less attractive plant.—A. O'N.

National Amateur Gardeners' Association.—The annual meeting of the Liverpool branch was held on February 14th, in the Common Hall, Hackins Hey, Mr. W. Histed presiding over a capital attendance of members. A long discussion ensued as to the best means of increasing the membership, and other ways likely to be of benefit to members generally, the unanimous opinion being that the branch was doing an excellent work, and that there must be no looking backward. Much regret was expressed when Mr. J. M. Smyth, who had been Secretary for the past eight years, announced his intention of resigning, owing to pressure of business. A feeling of satisfaction was experienced when Mr. Smyth gave his promise to attend and help forward the work of the Society in the capacity of Vice-President. Mr. A. W. Ardran was elected President, and Mr. McGregor, Secretary. The usual votes closed the meeting.—R. P. R.

Erica mediterranea hybrida.—This is one of the best of the winter-flowering Heaths, being bright in colour, and lasting a considerable time in flower. It commences to bloom in December, and continues till the end of April, and is bright and charming at any time during that period. The flowers are of a pale mauve when first expanded, but deepen in colour with age, and are produced in great abundance along the whole length of the previous season's growth. It grows freely in almost any soil, provided it does not contain lime, and soon makes a strong, robust plant, which shows to advantage in any situation. For preference it should have a warm, sheltered position, and be so placed that it may receive the full benefit of all the sunshine obtainable during the winter months, which will make a great difference to the size and colour of the flowers. It is easily propagated by cuttings, which root readily and soon form good plants.—C.

Nuts as a Food Staple.—The United States Department of Agriculture has of late been giving especial attention to the cultivation of Nuts, and it has come to the conclusion that the Nut trees of the world would feed from two to three times the present number of inhabitants. Especially interesting are the facts furnished by the Nut specialists. There is no product that requires so little cultivation as the Nut, and none is more wholesome as a food staple. An orchard of 2000 trees in California yields every year over 24,000 lbs. of shelled Nuts. The American Government is making a special point of recommending Nut culture. In New England the abandoned farms are being planted with Nut trees, and the worked-out ground is found to furnish nourishment enough to cause the Walnut, Butternut, and Chestnut to flourish abundantly. Farmers in nearly every north-eastern State are, says a contemporary, planting Nut trees with their Peaches and Pears, and are utilising the hillsides, where nothing else will grow for Nut orchards.

Examination in Horticulture.—Intending candidates for the Royal Horticultural Society's examination, to be held on April 25th, may obtain all particulars from the Secretary, R.H.S., 117, Victoria Street, Westminster.

Rosherville Gardens.—The sale, by auction, of Rosherville Gardens, long advertised as "the place to spend a happy day," is announced to be made next month, and unless some at present unexpected development occur the estate may fall into the hands of the builders.

Canadian Apples.—These are in competition with American fruit in the London market. Shipments during the month of January were particularly heavy, in one day 7524 barrels, containing 22,572 bushels, having been unloaded. A fine sample of Newtown Pippins was among the importation. The culture of this variety in Canada promises more extensive shipments in the near future.

Tasmanian Apples.—Tasmanian Apples at their best are excellent, and arrive at a time when other supplies are either scarce or comparatively inferior. During the coming season, which is at its best in May, we are to have 150,000 cases. The success of the Apple trade of the Colony is largely due to Dr. Benjafield, who went thither about nine years ago, and is now a large grower and exporter. Some of the Tasmanian Apples realise from 15s. to 20s. per bushel box on the London market. These prices do not, however, exceed the highest obtained for the best New York Pippins, and the Blenheim Oranges.

Californian Fruit Growers.—Fruit growers in California furnish an object lesson of what can be done through true co-operation. At the recent meeting of the Californian Fruit Growers' Association the fact was developed that prospects are favourable for bringing into the Association 75 per cent. of all interested in the production of dried fruits. After the 1st of April the work will be under full swing, and plans perfected for handling the coming crop. It is worthy of note that a resolution was adopted against the pending reciprocity treaties now before Congress as "inimical to the best interests of California's great horticultural industry."

An Orchid Home.—Mr. Wells, author of "Three Thousand Miles Through Brazil," says:—"There is no question whatever that the majority of the Orchid family do prefer hot and humid regions; yet, nevertheless, I have myself seen wild Orchids growing amid a rachitic vegetation upon the lofty summits of sierras, and also amidst the drought-resisting vegetation on the summits of the arid table lands of Brazil—regions which are especially notable for their generally very dry climate. There, I confess, to my own astonishment, I have, at times, found Orchids in abundance—not parasites, but really Orchids. As to the second observation, I would point out that, despite the now huge population of Rio de Janeiro, and the eternal hunting for Orchids the woods around that city still abound with Orchids. Moreover, the lovely gardens of Rio will show how happy and healthy an Orchid can be, even when transplanted from the wilds of the forest, and tied by a string to a tree in a suburban garden, living and blooming for years in the company of human beings."

A West End Fruiterer on Cape Plums.—Rich, red, ripe Plums, even in the summer and early autumn, have an alluring charm all their own, and distract the eye from humbler Cherries and comparatively common Strawberries; but what is to be said for the punnets of beautiful Cape fruit now displayed amid wintry surroundings in the West End shops? Brilliantly coloured and purple-bloomed, in appearance as well as flavour, they challenge the home-grown article, and who, wanting Plums out of season, grudges 2s. a basket of six? A mere bagatelle compared with the prices of English Pines, or the neighbouring Asparagus at 27s. the bundle of a dozen or so spears. "And they sell rapidly," quoth a West End fruiterer to a "Leader" representative, "because you see, really, they're not expensive, and are delightful to eat. How long does the season last? Well, I expect we shall be able to get Cape Plums until the English ones are on the market. And after the war—ah, the war plays havoc with us!—they will possibly be cheaper than they are at present. Cape Peaches and Apricots are cheaper, but the flavour is not quite so good; but they grow almost wild out there. A little training and grafting, you know, and the Cape fruit would be as good as the English at a fourth of the price. Ay, it is a pity our young men don't start fruit farming out there—but, well, it's an ill wind that blows nobody good, and the war may at least open their eyes to the possibilities of trade."

Florida Oranges.—The Orange groves in Florida have been visited by a severe frost that has considerably damaged this year's first crop. Bonfires have been started amongst the trees, and it is thought that by this means a second visit can be warded off, and much of the fruit saved.

Tobacco in the Strand.—The attempted introduction of Irish grown Tobacco recalls the fact that the fragrant weed once flourished in Lord Burghley's garden in the Strand. This was in the distant days of Gerard, the famous old botanist, who lived about the time Sir Walter Raleigh introduced the Tobacco plant.

Reading Gardeners' Mutual Improvement Association.—Notwithstanding the very severe weather, a large attendance of members was present on Monday evening last to hear Mr. T. Neve of Sendlesham House Gardens give a paper on the renovation of fruit trees, especially Apples. The lecturer dealt with his subject in an exhaustive manner, his remarks on branch and root pruning, manuring, and watering, being of a very practical character. These were made more interesting by a series of photographs of old trees, which had been renovated, in full bearing. An interesting, and at times animated, discussion followed, in which Messrs. Chamberlain, Powell, Fry, Purkis, Parsons, Blake, Cretchley, Bryant, and Turner took part. A splendid collection of Apples was staged by Mr. R. Chamberlain, the well-known fruit exhibitor, of The Gardens, Cressingham. Although late in the season the fruit was in splendid condition, the exhibit including Golden Noble, Lane's Prince Albert, Wellington, Rosemary Russet, Royal Russet, Cox's Orange, Rymer, Gascoyne's Scarlet, and the Melon Apple. On the proposition of the Chairman (Mr. Fry) a hearty vote of thanks was tendered to Mr. Neve for his excellent paper, and to Mr. Chamberlain for his exhibit. Four new members were elected.

Shropshire Horticultural Society.—The annual meeting of the members of the Shropshire Horticultural Society was held on Monday afternoon, the Mayor (Mr. R. S. Hughes) presiding over a large attendance. The Mayor congratulated the members on the extraordinary success which attended the Society's last show, and on the fact that the receipts for the past year exceeded any previous record by considerably over £200. Mr. W. W. Naunton (one of the Hon. Secs.) presented a most satisfactory annual report from the Committee. The Assistant Treasurer presented the statement of accounts, and pointed out that the total receipts for 1899 amounted to £4739 10s. 11d. The profit on the summer Show amounted to £1050 13s. 5d. The balance in the bankers' hands on December 31st, 1898, amounted to £1898 15s. 3d., and on December 31st, 1899, to £2149 9s. 10d. The actual receipts on two days of the summer Show (excluding subscriptions)—taken at gates, first day £879 14s. 9d., second day £1852 19s. 6d.—amounted to £4154 3s. 2d., and the actual payments to, on account of summer Show alone, £3648 13s. 7d. The Society's total receipts for twenty-five years amount to £65,197 10s. 3d. The first year's receipts were £791 12s., as compared with £4739 10s. 11d. last year, which was about six times as much. The donations and gifts made by the Society amounted to £5840 10s. 6d., and in addition to the balance of £2149 9s. 10d. in the bank, the Society own land situated between the Quarry and the Friar's Bridge.

The weather during the first part of the week was remarkable for snowstorms, strong winds, and frosts; the latter part being milder with bright sunshine and frequent showers.

FRUIT GROWING IN SOUTH WESTMORELAND.

ANY stranger visiting Kendal Market on a Plum Saturday morning would be astonished to see the long string of carts full of Damsons, and would naturally ask where and under what conditions they are produced. The answer would no doubt be, "You seem surprised at the quantity of fruit here displayed, but this does not represent a tithe of what is grown in the neighbourhood, the majority being sold growing—to the dealers who come from the thickly populated districts of Yorkshire and Lancashire." Visitors to the Lake district will no doubt be acquainted with the route (by road) between Grange and Bowness; probably a more picturesque bit of country can scarcely be found.

Taking either side of the great limestone cliff of Whitbarrow you find most of the hedgerows planted with Damsons, which in spring are beautiful in their purity of white blossom, and in autumn generally laden with handsome black fruit. The mode of propagating the trees and the subsequent culture are of the simplest; any elaborate preparation is looked upon as money ill invested. We must, however, bear in mind that the natural conditions seem in every way exactly suited to the requirements of the trees, with one notable exception—spring frosts. Generally the hill sides are planted, or properly speaking the hedgerows along the hill sides, and it is with these trees we will deal first.

The young trees are all grown from suckers, worked plants being regarded with great disfavour. Suckers are produced promiscuously all round the older trees, and are generally taken up, placed in a small nursery, kept to one stem until of suitable height, and then allowed to branch. When a good head is formed they are placed in their permanent quarters. When finally planted (generally close to a hedge) a pick is taken and the surface of the ground lightly loosened, the young tree has its roots spread evenly over the surface, and a cart of soil follows from which just sufficient is taken to cover the roots. The tree is then staked securely, and usually receives no more attention until the fruit is gathered, although in some cases the newly planted trees are headed back; but opinions vary as to whether cutting back is advantageous or the contrary.

Simple as are the methods of cultivation, what are the results? First, good trees on their own roots, which fruit more freely than worked ones; second, owing to the roots of the trees being kept near the surface, sturdy growth perfectly matured ensues; and third, a fair profit, which enables the farmer to meet the contingencies of the times.

Many persons will no doubt propose more elaborate preparations for the young trees, while others will say, Why not have worked trees? In answer to the first, we are told that lavish preparation of the soil results in strong immature growth, which does not blossom, and worked trees often end in failure because they fruit more sparsely than those on their own roots, and would be ruinous owing to the much larger stones that the fruits contain.

Now a word or two as to spring frosts which destroy so much blossom. I am quite sure the majority of growers prefer a moderate crop on their trees, and look upon a bit of frost as a blessing in disguise. A few years ago the crop was so plentiful that it could not be sold at 6d. per score pounds, while when a moderate crop is produced prices range from 3s. per score, and are then remunerative; one season as high as 7s. 6d. was asked, and buyers were pleased to give it.

Many trees are planted in the hedgerows on the moor. They are growing amongst peat, but the roots soon come into contact with clay, which no doubt enables them to obtain what is wanted during the various stages of growth. Sandy warp also produces good fruit, but undoubtedly the best results are obtained from trees planted at higher altitudes.

Apples are also grown in considerable quantities. Many of the varieties are of local origin and moderate quality. Some growers have come to the conclusion that the newer Apples are superior to their own, and are accordingly planting varieties of good merit, but the majority are content with worthless seedlings, the fruit of which is hard to sell (retail) at ½d. per lb. Many of the Apple orchards are in a deplorable condition; old worn-out stumps of trees infested with moss and lichen, and while adding in part to the picturesque scenery, have nothing to recommend them from a monetary point of view. The Westmoreland County Council has so far provided no instruction in a horticultural sense, but some of the landowners have recently planted orchards with up-to-date varieties, which in a short time must prove valuable object-lessons. The earlier varieties of Pears are also grown in fair quantities, but do not come to the same perfection as on deeper soils; probably the natural soil is too hot and dry for their well-doing.

Plums are grown in considerable quantities, Victoria being the

chief variety. Pond's Seedling also does well. Green Gage crops freely, and the growth of the young trees is generally sturdy, well matured, and of just the right strength for producing buds plentifully.—W. J. I.

P.S.—To show how trees on own roots are appreciated a grower proudly showed me a rooted layer of Victoria Plum, in the hopes it would throw suckers similar to his Damsons.—W. J. I.

OVER-FED CHRYSANTHEMUMS.

EACH season we are careful to note failures as well as successes in regard to the popular autumn flower, and considering the number of cultivators that now exist who grow the plant especially for what may be termed big blooms, the former are in too great a proportion to the latter. So many grow the plants well up to a certain stage, then the troubles begin, and as we observe things, the principal cause is the too free use of stimulants, especially those of a concentrated or "artificial" nature. Over-anxiety as to whether the blooms will be open at a given date has led to nitrate of soda being used, not wisely but too well, so as to burn the roots and prevent proper development of the blooms, and also trusting this strong fertiliser to the hands of the young in experience, but whose enthusiasm teaches them that if from half an ounce to a gallon of water such wonderful results accrue, what marvellous blooms will spring from a double dose.

In mixing the soil, again, we have known these concentrated forms of manures to be added in such quantities that roots absolutely refuse to move into the new earth, and even the old roots have been killed thereby giving the plants a check from which they are not likely to recover. Why Chrysanthemums should want so much more feeding, than most other plants grown in pots we do not know. They carry big leaves certainly, but they usually get a fair quantity of earth for root space.

Two or three striking illustrations occurred within my knowledge last autumn as to the wisdom of feeding. One especially was that of a young gardener who grew a few Chrysanthemums to obtain large blooms for the first time. He rooted cuttings, duly potted them, and attended well to the watering during a trying summer, trained three growths to each plant, and did not "top" them on fancy dates, but let them grow their own natural height. Guanos were unknown as far as his small garden was concerned, and he was satisfied with the neighbouring meadow to collect his stimulant from cow and sheep manure. This was applied weak and often when the bloom buds were swelling; and superb blooms of Lady Byron, Austral Gold, Pride of Madford, Phoebus, and other well-known Japanese varieties resulted. A near neighbour was cultivating a large collection for purposes of exhibition. These were grown with intelligence and care, and throughout the season the plants were talked of and envied on account of the giant stems and huge leathery leaves. In due time they were housed, but by the time the marvellous flowers were required a change had come over the scene. The blossoms opened imperfectly and contracted, colourless and thin. These plants had been fed with all kinds of nameless mixtures, and the growth so pleasing to the eye was really soft, and what should have been "wood" was "pith." As gardeners do not differ in various localities in the matter of enthusiasm for the Chrysanthemum, these ways can be taken as similar to those in other districts, so that failures may be thus multiplied. Of all plants we know the autumn queen is the most overgrown, or rather overfed.

It would serve a useful purpose if, now that another season is before us, readers of this Journal stated their views upon this and other phases of culture. By this means, one is sure many failures might be averted during the coming autumn. Our experience is that white Chrysanthemums are the more tender rooted, and will not take stimulating manures unless in a very weak state. High-coloured varieties, again, have roots of a very sensitive nature. Some of the coarse varieties like Etoile de Lyon are not so readily overfed, nor are the yellows. It may be found also that the incurving Japanese like Oceana and Australie, with their thick florets and stout foliage, are less likely than most varieties to be spoiled by feeding. But generally, we believe using stimulants to grow Chrysanthemums has become a fad which is very much overdone, and our advice to cultivators who have hitherto not succeeded in so great a measure as the wish to look to this as a probable cause, and apply the remedy in future.—SPECIALIST.

ASHTEAD PARK.

YEAR after year the complaints become more numerous and more emphatic that owing to the deleterious elements in the atmosphere gardening in the neighbourhood of the metropolis is rapidly becoming an impossibility. It is, however, a fact that within, say, a fifteen mile radius of Charing Cross there are some of the best appointed gardens, containing the most excellent products of the gardener's skill that are to be found in the country. One establishment may be celebrated for this product or for that plant, and the aggregate brings one almost to the ideal of perfection in every phase of the art. We look, and not in vain, to the specialists to maintain the prestige of metropolitan gardens and gardening. There may be fogs and there may be smoke, but to overcome them, or rather their baneful effects, we have the determination of the enthusiastic cultivator, and so far the latter has scored. The troubles and trials may grow in numbers yearly, but with few exceptions they succumb to concentrated skill. Even within the four-mile circle of Charing Cross the interested searcher can find places where excellent fruits, flowers, and vegetables are produced, and it will probably be many a year ere this ceases to be a fact.

Of the estates where one can find many features of high

of vehicular traffic, and which the deer cross and recross at will, as there are no flanking fences to the roadway. The whole area of the park land is handsomely wooded with various kinds of forest trees, the major portion which thrive wonderfully well. Some of these are of considerable age, while others are of a comparatively modern date of planting. This variation creates the impression at one moment that the estate is young, and at another that it is old. As a matter of fact the latter would be the more correct description. Successive owners have done much not only to enhance its value (if such were desired) from a timber producing point of view, but also to add to its arboricultural beauties, and it is now rich in interest and in continuously pleasing features.

THE TERRACE GARDEN.

In the immediate neighbourhood of the mansion there is no, except what is known as the Terrace Garden, appreciable quantity of formal bedding, the more natural beauty of sweeping lawn and handsome trees being relied upon for affording suitable attractions. In the photographic reproduction (fig. 41), this particular garden may be seen, and its formal design is quite in consonance with the balustraded terrace upon which it stands and the mansion near by.

Photo by Parrett,

Leo herhead.

FIG. 40. — ASHTEAD PARK.

average quality as well as a decided specialty there are many, and amongst them must be included Ashtead Park, the residence of Pantia Ralli, Esq., at Ashtead in Surrey. This, though comparatively close to London and within a very short distance of Epsom, is most charming in its delightful park, pleasure grounds, and gardens. In no section of the estate can there be found evidence of smallness; on the contrary, the broad acres of park with the herds of deer seem to speak of the size of an estate in the deepest recesses of rural England. The presiding genius is Mr. G. J. Hunt, whose fame as a Chrysanthemum grower is great, and in these plants of course we have the specialty of Ashtead Park.

THE PARK AND ITS OCCUPANTS.

There are entrances to the park from various points, including Ashtead and Epsom, and its wide expanse with clumps of trees in suitable positions and numerous individual specimens provide a spacious roaming space for the deer, which add materially to the picturesqueness of the scene. Bracken waving in the breeze in different parts of the undulating surface affords the protection that is demanded by these attractively graceful creatures. A curious fact, and one that cannot be very common, is found in this deer park, being bisected by a public road, which is used by a considerable amount

Needless to say the several beds, large and small, receive the plants customarily relegated to such positions, and which it is totally unnecessary to enumerate. From this garden may be had a most charming view of the park, the beauty of which is increased by the fact that the main vista is down a long avenue, but through the trees on either hand may be had some peculiarly attractive peeps. Occasionally from here the road crossing the park is observed shining white between the green, but in the main it is quite obscured.

THE PLEASURE GARDENS.

There are two distinct portions of the estate that are kept within the customary fence, and which are designated pleasure gardens. One of these is naturally quite close to the house, while the other is some little distance across the park. The former finds in its trees its greatest charm, and very beautiful they are in their diversity of form and the different shapes and shades of their leafage. There are, too, both shrubs and trees, which add to the picture by the aid of flowers, and these having been judiciously placed, are distinctly adjuncts that elicit admiration. In one position another feature has been recently added in the form of a Rose garden, and this, when the plants have become thoroughly established, will prove to be a constant source of fragrant beauty and interest. Pleasure garden number two is of a

totally different character, and to many eyes would be deemed the more attractive. The secret of its beauty may probably be summed up in the skilful manner in which the lake has been formed and in the singularly artistic manner in which the margins, banks, and other portions have been planted. Here is no apparent design, and yet there must have existed an excellent one, or there could not have been such perfect harmony. All kinds of weeping plants that would thrive clothe the margins of the water, whose surface is here and there broken by many water plants. As one passes from point to point one constantly finds fresh views to appreciate, which, if limited in extent, have nevertheless charms of their own. The boathouse at the head of the lake is constructed so as to harmonise with the surroundings, and Mr. Ralli may congratulate himself on such a charming garden in, to the writer at any rate, an unexpected situation.

THE CONSERVATORY.

As may be seen in the illustration (fig. 40), the mansion is built in what is termed the Italianesque style of architecture, and has every

disappointed, as neither will be found, simply because they are not desired. Medium-sized wood thoroughly solidified, and foliage of moderate dimensions, but very stout in texture and deep in colour, are the conditions aimed at by this redoubtable grower, for these mean, with proper attention, the finest flowers—refined in appearance, of great substance, over average size, and of rich colour. Such points as these have taken the Ashted Park flowers high up on the list at many exhibitions year after year, and it is more than probable will do so again in the days to come. Though, as in all collections of Chrysanthemums grown for exhibition, Japanese play the most conspicuous part nowadays, the incurved varieties are by no means neglected, and it is to be hoped, never will be. They may be stiff and formal in outline, but the true type has a refined beauty that could ill be spared, even amongst the monster Japanese that are now the rage.

UNDER GLASS.

Some portions of the indoor department were in a state of unrest owing to alterations in several of the structures, some of which had

Photo by Farrell

Leatherhead

FIG. 41.—THE TERRACE GARDEN, ASHTEAD PARK.

appearance of solidity and comfort. On the right will be observed the conservatory, whose dimensions are quite commensurate with the structure on which it abuts. Its internal equipment is ornately beautiful, and such as calls forth constant expressions of appreciation from every visitor. Few indeed must be the number of conservatories that are more handsomely appointed, and in which marble forms a more tasteful and exquisitely beautiful feature. Needless to say the whole is scrupulously clean, and the handsome plants are quite in keeping with the erection. Magnificent Palms and Ferns play the most important part in its embellishment, and the softness or deepness of green in the several plants finds a delightful foil in the materials used in the construction of the house.

THE CHRYSANTHEMUMS.

Having in mind the reputation that Mr. Hunt has gained for Ashted Park in the Chrysanthemum arena, our first thoughts on entering the gardens were for the autumn queen. This visit was paid while yet the plants stood in serried rows in the open, and the trio—two visitors under the wing of Mr. Hunt—was soon closely examining the plants from the surface soil in the pots to their topmost growths. The man who travels to Ashted Park in search of immense stems and leaves will probably leave again somewhat

done much service and were being renovated practically to the point of complete re-erection. Considering that there are the customary plant and fruit houses of varying temperatures there is little need to specialise at any length. It may, however, be noted that the various fruits are accorded that close attention which alone insures the attainment of the most satisfactory results. The Vines were looking splendid, and carried many a handsome bunch of well-coloured berries. Plants are, of course, numerous and varied, as must be the case where a large establishment has to have constant supplies for different purposes. Flowers must be forthcoming at all seasons, and all useful kinds are grown in varying numbers according to their utility as measured by the amount of appreciation they receive from the powers that be.

HARDY FRUITS AND VEGETABLES.

The walls surrounding the vegetable garden at Ashted Park are profitably occupied with fruit trees of various kinds, which give crops with pleasing regularity. Many of them were carrying splendid burdens at the time of my visit, Plums and Peaches being particularly noteworthy. Pears also find a place as do they in the open quarters. Apples in bush and espalier form are numerous, and from the condition of the trees it is evident they receive intelligent care from the gardener and his staff. Small fruits, such as Gooseberries and

Currants, with Strawberries, have a considerable amount of space devoted to them, as of course large quantities are required for various purposes. In the vegetable department everything is grown. Some kinds are, of course, not greatly in demand, while to others extensive breadths of ground are exclusively devoted. On every hand one may see evidences of sound culture, and, moreover, clear indications that care is taken in so laying out the ground that while nothing is so overcrowded as to suffer, space is not wasted anywhere. Thus the best returns are secured, and the whole reflects great credit on Mr. Hunt, to whom we tender thanks for a pleasant visit to Ashted Park.—H. J. WRIGHT.

LATHYRUS PUBESCENS.

THIS rare perennial Pea is now being offered in the shape of seeds, and it is likely that those who are admirers of the charming Lathyruses will take an early opportunity of securing a supply. As I had the pleasure of being, so far as I can ascertain, the first to flower this charming Pea in the United Kingdom, I think a few notes of experience may be of service to readers of the *Journal of Horticulture*. I received the seeds through the kindness of that ardent grower of new plants, Mr. W. E. Gumbleton, who kindly sent me a few of those he had received from M. Ed. André, of Paris. I was more fortunate than the others who had the good fortune to obtain them, and raised some young plants, but all of these save one fell victims while small to the greed of the slugs. This plant was kept in a pot during winter for the first year, and was eventually turned out with the ball intact into a warm border of light soil against the gable of an outhouse facing almost south-west, and covered with a trellis, over which the plant grew. The plant was not free in growth, and while it lived seemed half shrubby in habit. It grew to about 5 or 6 feet high, but was far from luxuriant in the way of covering the trellis. In winter it had only the protection of the dead stems of some perennial Asters loosely arranged over it.

When I realised that it was so scarce, I covered it with a mat in the winter of 1898-9, and to this excessive care I attribute the loss of the plant in the spring of 1899. It had made fresh shoots below the mat, and the late frosts in March of that year destroyed these, and no others took their places. Fortunately I had saved some seeds in 1898. These passed, with the exception of a few previously promised, into the hands of Messrs. Sander & Co., of St. Albans, who have raised plants from them. It appeared to me that it might be increased by cuttings in the hands of an expert propagator, and I think the firm mentioned was successful with a very few of the cuttings I sent to them. I do not think any of the young plants raised from my seeds have yet flowered, but I expect they will do so in May or June of this year.

There can hardly be two opinions as to the beauty of this Pea, whose racemes of small lilac-blue flowers are so pleasing in every way. If, as has been said, the leaves of the plants from which the seed now offered came are glaucous, like those of the Sweet Pea, they are not the same as mine, which had distinctly pubescent leaves. I may further remark that the seeds germinate very slowly, and that it is doubtful if *Lathyrus pubescens* is hardy in the greater part of the kingdom. It is so beautiful, however, that it is worthy of a good place, and of some little care.—S. ARNOTT.

FORCED RHUBARB.

BUT for the award of a silver Knightian medal to Mr. W. Ponpart for his splendid exhibit of Rhubarb at the recent Drill Hall meeting, he would have received a cultural commendation, for all members of the Fruit Committee agreed that no such exhibit of forced Rhubarb had previously been seen at any meeting, and the one in question displayed quality such as is very rarely seen anywhere. Of course a large market grower such as Mr. Ponpart is has a great quantity from which to select his stems, but it was evident that whatever the extent of the forced crop, the average must be very high indeed. It was noticeable that none of the varieties staged excelled Victoria in colour and in general excellence; but Daw's Champion is a rather more robust variety, having a trifle broader and longer stems, and is comparatively new. Hawkes' Champagne gave stems not much more than one-half the stoutness of those of Victoria, and did not excel the latter in colour. When the old Victoria is thus shown so good forced, and we know how excellent it is outdoors, it is evident that in Rhubarbs we have not made great progress.

But such stems as those referred to are not produced solely by forcing, howsoever excellent the method. Really they have to be made by high culture the previous year, on deeply worked soil, that is heavily dressed with manure, for Rhubarb is a gross feeder, and needs plenty of manure to create very strong summer growths, which in turn leave behind extra stout crowns, that alone will produce very fine

stalks. It is such treatment the breadths of roots lifted at Twickenham, and forced, receive. The forcing was in this case done in a low greenhouse sufficiently heated, the glass roof being densely covered with litter, which at once excluded light and cold. Of course the roots were set into good soil.—A. D.

ROYAL HORTICULTURAL SOCIETY.

SCIENTIFIC COMMITTEE, Feb. 13th.—Present: Mr. Bennett Poë (in the chair); Mr. Hudson, Rev. W. Wilks, and Rev. G. Henslow, Hon. Sec.

Elm-bark with Larvæ.—Mr. W. Brooks, of Weston-super-Mare, forwarded a piece of bark of an English Elm tree, with the following observations:—The Elm trees are attacked by an insect which is destroying them. Some of the trees are fine, nearly 100 feet high, and in their prime; others are smaller. The larger trees are attacked more especially on the north side; but the smaller all around the stem from bottom to top. One of the largest trees shed all its leaves in August, and it looks as if the whole of the trees will die."

Mr. McLachlan sends the following report:—"The Elms are attacked by the larvæ of a beetle. No perfect beetles are to be found in the bark sent, but there are numerous larvæ, each in a small cell, in which it will undergo its transformations. So far as can be judged from these larvæ, they are those of *Scolytus destructor*, so common in many places. In order to destroy them it was suggested, more than forty years ago, by the late Capt. C. J. Cox (who probably took his idea from the French), that all the old outer bark be pared off by a spokeshave or some similar instrument (the scrapings being of course collected and burnt), taking care not to injure the inner bark and wood. Dressings of dilute petroleum, repeated at intervals in dry weather, might also be of service. But the subject opens up a wider question—viz., whether the beetle is the cause of the condition of the trees, or only steps in where these latter are in a moribund state from some other cause. The writer of these remarks is inclined to think the beetles come as scavengers. At any rate in the case of tall old trees, probably already "stag-horned," it is practically useless to employ remedial measures, and the best thing is to cut them down and burn them, or at any rate cart them away at once from the vicinity of trees not already attacked. The bark of such old trees is usually riddled by the larvæ from base to top. When the trees are younger and less tall remedial measures, such as those suggested, might be tried. Even supposing the trees to be in an unhealthy state from some other cause, the attacks of the beetle must aggravate that state and hasten decay, and if these attacks could be lessened or averted there might be a chance of the trees recovering from the other conditions whatever they may be. But as a rule disease or decay have already proceeded too far before being discovered."

Fern roots attacked by grubs.—Mr. Burt, of The Gardens, Caenwood Towers, Highgate, sent a specimen of soil and grubs with the rhizomes of *Adiantum cuneatum*. Mr. Hudson observed that he was not unfamiliar with them. The specimen was forwarded to Mr. McLachlan, who reports as follows:—

"The grubs at the roots of *Adiantum* are those of a species of weevil probably *Sitones*, but I cannot commit myself to anything more precise without seeing the perfect insects. I should think the best thing to do now would be to turn out the plants from the pots, shake the old soil from the roots, and repot in clean earth, taking care to burn all the old with the grubs. When the foliage shows signs of being attacked go over the pots at night, turn each pot gently on its side, and shake the foliage over a sheet of paper. By this means multitudes of the perfect insects may be collected and destroyed, and the deposition of eggs prevented."

Orobanche on Pelargonium.—A plant in flower was received from Frances M. Cooper, Forest Road Gardens, Wokingham, described as having "established itself in a pot of *Geranium*." The latter at first showed no sign of diminished vigour; but now the specimen has come into bloom its host-plant seems to be weakly and its leaves are turning yellow. The plant does not seem quite like any wild species." The *Orobanche* was of a purple colour throughout, but not agreeing closely with any true British species.

FORESTRY AS IT AFFECTS MATERIAL PROGRESS.—The fertility of the soil and the material progress of the human race cannot be maintained without forests. It is not necessary for me to argue this point. It is sufficient to say that those who have watched the rapid deforestation of the middle and eastern States have for a number of years advocated some method of preventing the wholesale destruction of trees. In some of the older States there are areas once clothed with fine forests, but now being without trees have become almost valueless. These are being bought by the State at great cost, and an attempt made at reforestation. I have maintained, says a writer in a transatlantic journal, for years that Wisconsin should withdraw all her timber lands from the market. I am quite sure that all timber lands that have been sold by the State for the past ten years have been purchased solely on a basis of what the timber will be worth.

CAMPANULA GRANDIFLORA PUMILA.

THE stately perennial which is variously known as *Platycodon* or *Campanula grandiflora* is a favourite occupant of many gardens, its large, open, deep blue flowers being produced most freely. This and some of its varieties reach the height of 2 or 3 feet, and therefore either require permanent corners and similar sites, or they must be placed behind other dwarf-growing border plants. A variety possessing all the good qualities of the ordinary *C. grandiflora*, but with a considerably dwarfer habit, is that represented in the woodcut (fig. 42), *C. grandiflora pumila*. This grows 9 to 12 inches high, produces flowers similar to the type in size and colour, and forms a beautiful specimen, as it soon becomes covered with flowers. The plant is well adapted for culture in pots also, and is readily increased by seeds. Any ordinary garden soil that is not excessively heavy or wet suits it.

FLOWERING PLANTS FROM SEED.

RHODANTHES.

THESE half-hardy annuals are of an exceptionally showy character as pot plants for conservatory decoration in early summer. They are raised from seeds, which can be sown in the pots in which the plants are intended to flower, or the seedlings may be transplanted into the flowering sizes. Five-inch pots are the most suitable. In preparing these place liberal drainage at the base, and cover with moss or some fibrous material. The compost should be light and rich, and formed of equal parts of peat, loam, and leaf soil, with a little decayed manure and coarse sand. Fill the pots to within half an inch of the rim. Press smoothly, giving a gentle watering. When drained sow the seeds equally over the surface half an inch apart, and cover with a layer of fine compost. A little gentle heat will assist germination, and after the seedlings have pushed through the soil transfer to a shelf near the glass in a warm structure so as to encourage unchecked growth. The seedlings ought, however, to be gradually thinned to an inch apart. By the time the seedlings have attained a height of 6 inches, four neat stakes may be inserted at equal distances round the edge of pot, to which strands of matting should be attached for the support of the plants. Weak liquid manure will be an encouragement to growth, giving clear water as necessary. Still keep the plants on an airy shelf in the greenhouse. The individual plants are of slender growth, but in the aggregate produce a creditable display of bloom.

VERBENAS.

Verbenas are attractive bedding plants, and, though frequently perpetuated by cuttings from year to year, may be quite as readily propagated from seeds. Plants raised from cuttings are probably less vigorous, which is an advantage as regards flowering, but seedlings given plenty of room and not over-rich soil, may be expected to flower well. The chief colours in Verbenas are scarlet, blue, and white. A mixed packet of seeds of a reliable strain will produce these colours in good proportion. Prepare well-drained pans and fill them with a compost of sandy light soil. Smooth the surface and give a gentle watering with tepid water. Sow the seeds thinly, covering them with a layer of fine soil, which may be dredged through a fine sieve. Press it down smoothly, then place the pan in a brisk heat of 65°. Shade with glass and paper to maintain uniform moisture in the soil without the inconvenient recourse to watering before the seeds germinate. When the third leaf is formed on the seedlings transfer them to boxes of similar soil 1½ inch apart, and place near the glass to grow and strengthen. A further transplanting of the seedlings will be no detriment, but an advantage. Top those frequently that grow vigorously, as some seedlings are likely to do. Plant out in their flowering positions in beds at the end of May.

CARNATIONS.

Carnations are amongst the most popular of plants, and in addition to growing them from layers and cuttings, an interesting collection may be produced from seeds. The early flowering section represented by Marguerite Carnations respond most readily to this method of propagation by flowering the same year as sown. The ordinary Carnations may also be grown from seeds, but they should be sown in summer for flowering the following year. The Marguerite Carnations do not possess the qualities of the best named varieties, but they are, nevertheless, extremely useful for a variety of purposes. They usually commence to bloom in August, and continue doing so until frost stops them. The range of colour is wide, the flowers being mostly self-coloured, and they compare favourably in size to some of the choicer varieties of Carnations.

To obtain good plants which will produce a quantity of bloom seeds should be sown in February or early March. They may be sown in a pot or shallow seed pan, well draining the receptacle and covering the drainage with some of the rougher parts of the compost. This need not be of an elaborate character, but a simple porous mixture of

good loam and leaf soil free from worms, with silver sand mixed in. Fill the pot or pan to within an inch of the rim, pressing the compost gently down, and leave the surface smooth. Afford a supply of water through a rosed can, so that moisture is fully insured. When well drained sow the seeds on the surface, covering by dredging fine soil upon it. Flatten the soil with the base of a small pot. Place in a temperature of 60°, covering the pot or pan with glass and paper as a safeguard against undue evaporation. If stood on a moist warm base little or no water ought to be required until the seeds germinate. Admit light and air when the seedlings push through the surface, and increase gradually until the glass is entirely removed. Then stand the pot on a shelf close to the glass in order to prevent the stems of the seedlings elongating and weakening the plants.

This treatment is continued for a few weeks, giving water as necessary, until the seedlings are of a sufficient strength to be pricked out in fresh soil. This must be placed in boxes, having some drainage at the bottom, and be filled with soil similar in composition to that

FIG. 42.—*CAMPANULA GRANDIFLORA PUMILA*.

used for sowing, but a little rougher in character. It is, however, no hard and fast rule to use boxes, a bed made similarly in a frame on half-spent hotbed is an admirable place for the seedlings. Prick them out 2 inches apart, sinking them to the lower leaves. Under the influence of warmth and moisture, by keeping them in a rather confined atmosphere at first, the seedlings will soon root freely and grow strongly. Afford plenty of light, but prevent strong sunshine distressing them. As they become established, give increasing supplies of air, and less heat if the boxes are stood in a warm house. The conditions in a frame must be regulated by the supply of air. Give adequate quantities of water, but avoid overwatering, which will prevent the steady progress so desirable. Early in June the plants will be ready for planting out in a bed of fertile soil in an open position. The ground is best prepared by deep digging and breaking up the subsoil, adding material of a light character, such as potting soil and leaf mould, rather than rank manures. Strong plants may be placed a foot apart, weaker a little closer. The space between renders hoeing and weeding more readily

carried out. Numerous flower spikes will be produced in July, and those which have the tendency to lay on the ground should be lightly supported, so as to show off the blooms to the best advantage, as they continue to open from August onwards.—E. D. S.

ROYAL GARDENERS' ORPHAN FUND.

THE annual meeting of this most deserving Institution was held on Friday, February 16th, at the Essex Hall, Essex Street, Strand, under the presidency of A. W. G. Weeks, Esq. The numbers present were very limited, and included Messrs. W. Roupell, H. B. May, C. E. Osman, R. Dean, W. Poupert, A. Dean, J. F. McLeod, G. Gordon, J. Fraser, R. W. Alderson, H. J. Jones, J. Lyne, G. T. Miles, P. R. Barr, R. Cuthbert, J. G. Veitch, J. Melady, G. Richards, W. Bates, and G. Assbee. The notice convening the meeting and other preliminaries having been disposed of, attention was turned to the report of the Executive Committee for the year ending December 31st, 1899, which, with the financial statement, we give herewith.

REPORT FOR THE YEAR 1899.

In presenting their twelfth annual report the Committee have pleasure in congratulating the subscribers on a year of steady progress, the receipts from all sources showing an increase of £75 1s. 2d., which is satisfactory as indicating that, notwithstanding the great difficulty experienced in collecting subscriptions, owing to the many urgent appeals made to the benevolent for support in aid of the various patriotic funds, the Royal Gardeners' Orphan Fund has not only been able to hold its own, but also to increase the amount of the year's aggregate allowances made to the orphans. The revenue derived from subscriptions and donations, though showing an increase on the previous year, reveal a sensible decrease in the amount collected by local secretaries, a circumstance which the Committee can only regard with some anxiety, though they have reason to believe that the falling off in this source of income is only temporary, the result being due rather to the difficulty experienced in collecting subscriptions than to any slackening of the efforts of those who have hitherto done so much in support of the Fund. In common with most other charitable institutions, there is only too much reason to fear that the Fund may suffer from the pressure of the times during the coming year, but the Committee sincerely trust that the supporters of the Institution will assist them to the uttermost in their efforts to avoid such a deplorable contingency. To maintain the usefulness of the Fund unimpaired should be the aim of every one interested in gardeners and gardening, and the Committee more especially appeal to gardeners themselves to increase their efforts on its behalf by collecting small sums in their own districts.

The number of children who have been elected to the benefits of the Fund during the past eleven years is 113, and the total amount which the Committee has been enabled to distribute among the destitute orphans during that period is £7711 2s. 6d. The number of children now on the Fund is seventy-two, exclusive of those to be elected this day.

The Committee desire to acknowledge with grateful thanks the keenly appreciated services rendered to the Fund by Alderman Sir Reginald Hanson, Bart., M.P., who so kindly presided at the annual festival, and whose cordially expressed appreciation of the work carried on by your Committee, and his most forcible appeal for support on its

behalf resulted in a subscription list amounting to £602 12s., a result which was the more gratifying in that the festival had, for unavoidable reasons, to be held at a later period of the year than usual. The Committee have much pleasure in recommending that Sir Reginald Hanson be this day elected a Vice-President of the Fund.

It is with extreme pleasure the Committee make the announcement that Lord Battersea has very kindly consented to preside at the next festival, which has been fixed to take place on Tuesday, May 8th, at the Café Monico, 46, Regent Street, W.

The Committee sincerely deplore the loss which the Fund has sustained by the death of Mr. Sydney Courtauld, one of the Trustees, whose kindly support in its earlier days remains with the Committee a cherished memory. Mr. William Sherwood, the eldest son of the Treasurer, has kindly expressed his willingness to undertake the duties and responsibilities of the office of Trustee, and the Committee with great pleasure ask subscribers this day to confirm their choice.

By the recent death of Mr. Alfred Outram the Fund has also lost the services of another devoted worker, and the Committee a colleague whose genial presence and whole-hearted sympathy with the objects of the Fund will be greatly missed. The seat vacated by Mr. Outram's death has been filled by the election of Mr. Peter E. Kay, Clagmar, Church End, Finchley. The resignation of Mr. J. Cheal has also been received, and the vacancy filled by the election of Mr. W. R. Alderson, Bell Farm, Hersham Farm, Walton-on-Thames.

The members of the Committee who retire by rotation are Messrs. W. Bates, R. Dean, H. Herbst, H. J. Jones, W. Marshall, H. B. May, G. Reynolds, and A. W. G. Weeks; and Messrs. Bates, Dean, Jones, May, Reynolds, and Weeks being eligible, offer themselves for re-election. Mr. Whitpaine Nutting, 106, Southwark Street, S.E., and Mr. E. G. Monro, Covent Garden, W.C., are nominated by the Committee for the vacant seats.

The retirement of Mr. Marshall and Mr. Herbst is an incident in the history of the Fund which your Committee cannot but deeply regret, and their colleagues desire to place on record their high sense and appreciation of the valuable moral and material support which these gentlemen have so ungrudgingly rendered to the Fund. Mr. Herbst, one of the founders of the Fund, was one of the most constant attendants at the meetings of the Committee until struck down with illness, from which he has unhappily not yet recovered, and the Committee ask the subscribers to signify their appreciation of his good and faithful service by according him their special thanks. Mr. Marshall's services to the Fund as Chairman since the lamented death of Mr. George Deal in 1890, have been invaluable, and as a slight recognition of the uniformly courteous and efficient manner in which he has so long and so faithfully discharged the duties of his office, the Committee have the pleasure this day of nominating him for election as a Vice-President.

The Committee again most cordially acknowledge the generous and most practical manner in which the Treasurer, Mr. Sherwood, has continued to assist the Fund, and warmly thank him for his valued services during the past year. To the Auditors, Mr. Martin Rowan and Mr. Peter Rudolph Barr, the hearty thanks of the Committee are accorded for their patient and exhaustive audit of the accounts. Mr. Rowan is the retiring Auditor, and is nominated by the Committee for re-election.

The Committee are unanimous in nominating their Secretary, Mr. Brian Wynne, for re-election to that office.

(Signed) P. RUDOLPH BARR, } Auditors.
M. ROWAN.

These were taken as read, and in rising to move their adoption the Chairman made one of the shortest speeches on record, as he contented himself with the assertion that they were in all respects satisfactory. Mr. W. Roupell, in the capacity of seconder, was equally brief. The

Secretary at this juncture read a letter from the Bournemouth Gardeners' Mutual Improvement Association, which embodied a protest against more than one member of any family deriving benefit from the Fund at the same time. Mr. R. Dean proposed that the

letter be referred to the Executive Committee to deal with, asserting at the same time that where more than one member of a family were recipients subscribers might be sure that the case was urgently necessitous, or the Committee would not have recommended it. Mr. H. J. Jones supported this, as did Mr. Roupell, who was distinctly in favour of generous treatment, as he was of the opinion that it was desirable to do the utmost good with the funds at disposal, and thought that subscribers would rally round the Institution in proportion to the amount of real service that it did for the orphans for whose benefit it was constituted. These little points having been disposed of, the motion that the report and balance-sheet as in the hands of those present be accepted was carried with acclamation.

Mr. Weeks then rose to propose that Alderman Sir Reginald Hanson, Bart., M.P., who it will be remembered presided at the Society's last annual dinner, and which was such a signal success, be elected a Vice-President of the Fund, and further that Mr. William Marshall be elected to a similar position. The latter gentleman has long been Chairman of the Executive Committee, but has unfortunately felt compelled to relinquish that position owing to its taking him out at night, which was detrimental to his health, and it was therefore desired that, while regretting the loss of his valuable personality in the active work of the Society, that he be added to the list of Vice-Presidents. Here again Mr. Roupell was seconder, and the proposal was carried unanimously.

The much regretted death during the past year of Mr. Sydney Courtauld made it necessary that a fresh Trustee should be elected, and the Chairman nominated for the position Mr. William Sherwood, son of Mr. N. N. Sherwood, the highly esteemed Treasurer of the Institution. Mr. R. Dean seconded this proposition, and there was no dissentient voice when it was put to the vote. It must be superfluous to say that Mr. N. N. Sherwood was re-elected Treasurer, and heartily thanked for the valuable services he had rendered to the Society in the past. As the rules of the Fund necessitate one Auditor retiring annually Mr. M. Rowan (of Carnation fame), who is associated with Mr. P. Rudolph Barr in this capacity, was proposed by Mr. G. Assbee for re-election. Mr. W. Poupart was the seconder, and everyone present was emphatically agreeable, as was evidenced by the unanimous, "All."

Mr. Alexander Dean proposed that Messrs. W. Bates, R. Dean, H. J. Jones, H. B. May, G. Reynolds, and A. W. G. Weeks be re-elected members of the Committee. In support of these nominations he alluded to the satisfactory condition of affairs in general, and considered this sufficient evidence as to their suitability for service. He further intimated that in case there came a time when the Institution was overburdened with funds they should make orphans over seventy years of age eligible for benefits, and coupled with the suggestion that both the Chairman of the meeting and his brother, Mr. Richard Dean, having passed the allotted span, might be the first recipients. Mr. Weeks intimated his willingness to accept of this. The portion of Mr. Dean's proposal relating to the Committee having been supported by Mr. J. Fraser, was carried, and we may assume that the second portion will stand over for the next half century or so. Mr. J. G. Veitch proposed, and Mr. P. R. Barr seconded, that Messrs. Whitpaine Nutting and E. G. Monro be elected members of Committee in place of Messrs. W. Marshall and H. Herbst, who resigned. This was carried. In reference to the last named gentleman, Mr. Weeks proposed that he be heartily thanked for the active support he had accorded to the Society for many years, and this receiving the support of Messrs. H. B. May and W. Bates, was also carried unanimously. On the motion of Mr. Weeks, seconded by Mr. Assbee, Mr. Brian Wynne was re-elected Secretary for the ensuing year, and both speakers eulogised the services Mr. Wynne had rendered. Messrs. W. Bates, W. Poupart, R. W. Alderson, J. F. McLeod, R. Dean, and H. J. Jones were then elected scrutineers of the ballot, and the meeting was adjourned until 4.30.

RESULT OF THE BALLOT.

Punctually at moment stated, Mr. W. Poupart, on behalf of the scrutineers, announced that the ballot had resulted as follows:—Hilda K. M. Rogers, 506; Aaron Hall, 470; Winifred Moxham, 429; Charles A. Dranfield, 427; John Baird, 254; Edward White, 237; George W. Stevens, 153; Margaret M. Wood, 148; Sarah C. E. Langley, 135. These, therefore, were elected. It was then announced, and was splendidly received, that the finances were so satisfactory, that Arthur G. Stephenson, 130; Ernest S. Henderson, 105, who were also on the balloting paper; and Frederick G. King, J. G. Riddle, and Mary Alice Wood, whose nominations had come too late for inclusion, but which were known to be deserving, could be placed on the Funds, and this having been put to the meeting, was carried with acclamation, and we may add, fittingly crowned a successful meeting, which was brought to a close with a vote of thanks to Mr. Weeks for his services in the chair.

BURNING LEAVES.—The Board of Health of Plainfield, U.S.A., is said to be considering the question of adopting a rule which will prohibit the burning of leaves within the city limits, as it is claimed that the practice is conducive to much ill-health during the autumn season. Several physicians have said that the smoke and smudge which come from burning leaves are the cause of many of the ailments of the throat, lungs, and eyes.

DEATH OF MR. P. W. FAIRGRIEVE.

MR. PETER WALKER FAIRGRIEVE died suddenly at Dunkeld House on Thursday, the 15th inst., where he has been head gardener for a quarter of a century, first under the late Dowager Duchess of Athol, and for some years under the present Duke of Athol. The sad intelligence of the removal of this talented and popular horticulturist will be received by many friends with deep regret. He was a great enthusiast in all matters associated with gardening, but distinguished mostly for the part he took in the development of hardy fruit culture, and has been a large exhibitor of these fruits, as well as a lecturer

FIG. 43.—MR. P. W. FAIRGRIEVE.

on their cultivation. At Dunkeld Mr. Fairgrieve had considerable scope and favourable opportunities for testing the qualities of outdoor fruits, and the proving of such as were suited to the northern climate. The fine walls, shelter, and good soil and position of the garden were taken full advantage of; while the attention to cultural details gave evidence of Mr. Fairgrieve's knowledge and unremitting attention to that most useful branch of gardening.

The great gathering of gardeners which was held some years ago from all parts of the country is well remembered by most of us. The keen investigation of trees and fruit, and the discussions which took place, gave much pleasure and instruction to all. A splendid entertainment was given in the Town Hall of Dunkeld to the visitors in the form of a banquet. The Dowager Duchess backed Mr. Fairgrieve in his efforts to render success complete. Mr. Fairgrieve was a Gallowayshire man. His experience in gardening was wide and practical. After years of apprenticeship and journeyman the deceased went as foreman to Wemyss Castle, Fifeshire. He went as foreman to Dunkeld, then as head gardener to Duncrub, near Perth, whence he returned as head gardener to Dunkeld.

THE YOUNG GARDENERS' DOMAIN.

BITS FOR THE BOTHY.

FIGHTING THE BORES. (Continued from page 124.)

"WHAT a bore!" This from many a youth at the mere thought of studying in any shape or form; and this from those who are really the best of good fellows. There is always something very taking and very contagious about these "happy-go-lucky" kind of boys, who, without words, tell you in the language of eyes and actions, that this old world of ours is a very jolly kind of place to live in. We could not do without them—these veritable sunbeams of life, but they must be caught—trapped into a steady purpose, instead of flickering out their existence on a scene behind which lays so many stern realities. Their thoughts, plans and actions run freely into any mould, but will not keep shape. This must not be. One particularly bad case was doctored by the "O. B." some years ago, and, happily cured; otherwise the question of isolating the patient to prevent infection by this high fever of life would have been seriously considered. The course of treatment pursued will be sufficient recipe for others to cure themselves if they will adopt it.

"A—, I want you to copy out this list for me, after tea; take it into the bothy." A— took it with heightening colour and, apparently, some suspicion. After tea a visit to the bothy found the decks cleared and A— in action, literally sprawling spread-eagle fashion over the foolscap as his mouth twitched and twisted in sympathetic movement with the pen. Sitting down, our young scribe was watched and waited as he twisted and wriggled to a finish; muffled sounds overhead testifying to the enjoyment extracted by comrades aloft from the martyr's sufferings below. The pen, of course, was "a bad 'un," and he "could do it better with a pencil." "Will it do, sir?" "Yes, very well (it answered present purposes); "but you want practice. You are going to be a head gardener, some day, are you not?" "Yes, sir," as the eye which showed a suspicion of moisture brightened considerably. "Well, you know a good head gardener must be a good scholar, so practise an hour's writing every week night, except Saturday night, to the end of the month, and I will look in and help you—say from seven till eight o'clock."

Poor A—, he would never have tackled that bore singlehand, but between us we ousted him; yet it is believed that had the six consecutive nights in the week been insisted upon he would not only have run away, but his fighting days would have been over. This

small but important victory was followed by a regular monthly plan of campaign, the time being increased by half an hour, with certain variations in the tactics to keep the bores at bay. Many attempts were made by the enemy to recover lost ground, and it was evident enough to an old soldier that this young recruit was the hero of a hundred fights. Ere a new year's day came round the field of operations was secure, and very little scouting by the "O. B." was necessary. Just a little scheming to make the monthly plan fit into the season of the year and critical reviewing to mark progress. At the new year A—was started with a diary and a box of drawing tools as longer range missiles for one who had gone from strength to strength, and was now more than conqueror. Just the plain, unvarnished picture of a young life. No more. There is pleasure and pride, however, in adding the sequel. The A—now occupies a higher position than his one time master.

"Humph!" some will say, "don't see where we come in." Well, young friends, this is where you come in—in this "Domain," and can we persuade our esteemed commander-in-chief, the Editor, to enlarge it in his own good time by giving the old mentor a little more license, and yourselves a little more liberty, it will be our mutual prerogative to "take occasion by the hand and make the bounds of freedom wider yet." You will, as well, be brought into touch—direct touch—with the great world of gardening whose future is your heritage. A great responsibility, is it not? This future—viz., your future and the future of gardening, which is slowly but surely being interwoven by the hand of Time; but, "Forewarned is forearmed," or should be. That many already enjoy all the good counsel and sympathetic assistance their own particular officer is able to give goes without saying; but there are, in the aggregate, battalions of recruits who are wholly, or in part, deprived of this help by unavoidable circumstances remains, nevertheless, a fact.

Apart from this, no man, young or old, can march with the times unless he keeps himself posted up in current events which directly or indirectly concern him. Every bothy in the kingdom should have its weekly budget of high-class gardening news. However it is obtained, it must be had. In many cases, of course, it goes from the gardener's house to the bothy, oftentimes with the injunctive threat, "If you lads don't keep this paper clean, you won't get it any more." It is an old trick with these gardening papers in the bothy of tearing themselves, losing their leaves, gathering up all the grease spots and dirty finger-marks—doing all they can, in fact, "just to get chaps into a row." Sometimes the foreman "whips" it off to his room, and gorges it by himself; at other times it never comes at all. To sum up, this spasmodic supply of gardening literature to the bothy is very unsatisfactory. 'Tis strange, passing strange, that what should be first is thought of last, and perhaps least.

The curious part of the matter is that there is no grudging of pence by our lads of the bothy for reading matter. In some a daily paper and sundry weeklies are common enough, whilst the more luxurious magazines, with their stores of light or heavy mental ammunition, have come to be almost a necessity; but there are lots of bothies, half of the whole garrison probably, in which a gardening paper, if it does not reach them through a charitable channel, never reaches them at all. Why is it so? Young Britons, of course, want to know how the war is getting on, and how the world wags generally. That naturally accounts for the newspaper; and then there are "Scraps," "Tit Bits," and "Comic Cuts," for each boy's particular taste. All that is right enough we know; but what we want to know is, where the literature of your life's work comes in? Every bothy should have its high-class gardening paper every week, and all the week; and if it is finger-marked, dog's-eared, and generally dilapidated by the time the fair fresh number appears, it will at least show that it has done its duty, and the boys have done theirs. Read the war news, boys; laugh at and enjoy your pennyworth of the light side of life if you will, or share the brief triumphs of "'tects" and mystery-mongers if you must; but do not ignore the gospel of your own high calling! Still, some will say perhaps, "Oh! we can't afford a gardening paper after buying so-and-so, and so-and-so." The obvious course, then, is to buy it first; and if you still cannot afford it amongst you, perhaps your sharper eyes can see that way of affording to do without it, which is not in sight of—THE OLD BRIGADIER.

(To be continued.)

CANNAS.

THESE beautiful plants do not seem to be so universally grown as they deserve. Their fine spikes of bloom, of rich variable colours, add greatly to the beauty of the greenhouse during the spring and summer months. To have plants in flower in spring a number of old plants must be shaken out immediately, carefully removing as much soil as possible, and cutting off last season's growth. Divide the roots, and place into well-drained 5 and 6-inch pots in a compost of rich fibrous loam, with half the quantity of peat, and a liberal addition of broken charcoal and coarse sand. They should then be placed in a house in a moist growing temperature, or a heated pit would answer the purpose equally as well. Shade when the sun gets very bright, and syringe frequently, which will keep their worst enemy (red spider) in check. When the flower spikes show colour transfer them to a cooler house, where they will remain in flower for a considerable length of time.

There are a great many varieties, but some of the best are Queen

Charlotte, Marceaux, Italia, Asia, aurea, Duchess of York, Admiral Avellan, and C Henderson. As the plants finish flowering put them in a cold frame, and eventually store on shelves in a cool house or shed, where they are protected from frost.—E. B.

FRUIT FORCING.

Cucumbers.—In houses where red spider has appeared on the winter-fruited plants, coat the hot-water pipes with sulphur and lime in equal parts, formed into cream with water, heating the pipes to as near boiling point as possible for a couple of hours on a calm evening, the house being kept close, and then allow the pipes and house to cool down to their regular temperature. The foliage must be thoroughly dry. The same process may be repeated in the course of a few days. It is generally effectual against white fly, thrips, and mildew, as well as red spider.

Plants in bearing should be examined once or twice a week for the removal of bad leaves and exhausted growths, thinning the shoots, stopping, and clearing them of old or deformed fruits. The thinning of the shoots, and encouraging young in place of spent growths, is the way to keep the plants in continuous bearing. Stop the growths a joint or two beyond the show of fruit, but avoid overcrowding. Maintain the bottom heat steadily at 80°, the night temperature at 65° to 70°, 5° less in severe weather, 70° to 75° by day, rising to 80° or 85° from sun, and closing early in the afternoon so as to run up to 90°, 95°, or 100°, damping the paths and other surfaces in the morning and early in the afternoon.

Young plants should be planted in ridges or hillocks, about 2 feet wide and 10 inches deep, formed of turfy loam laid up sufficiently long to destroy the herbage, mixing with about a fourth of well decayed manure. Plants for trellises should be trained with a single stem, secured to a stick tied to the lowest wire of the trellis, rubbing off the laterals as they appear until the height of the trellis is reached. The plants in pits and frames should be stopped at the second rough leaf, and the resultant growths at about every foot of extension. This will give plenty of shoots for bearing, which must not be crowded, and should be stopped at a joint or two beyond the show for fruit. If the sun be powerful, and the plants show indications of flagging, shade for a few days.

Pines.—*Plants Starting into Fruit.*—Those plants started at the new year by an advanced temperature and moisture will now be showing fruit. The temperature about them may be maintained at 65° to 70° at night, and 75° to 80° in the daytime under favourable circumstances, ventilating at 80°, allowing an advance to 85°, and close about that figure. With fruit advancing the plants will require more water at the roots, examining the whole stock once a week, but supplying it to such plants only as need it, always in a tepid state, and with a little stimulant in it, as guano or some approved fertiliser. Recently started plants to afford a succession of fruit should have a night temperature of 65°, and 70° by day, which, with a rise of 10° to 15° from sun heat, will be sufficient for them for some time longer.

Vines.—*From Eyes.*—Buds inserted a short time ago have rooted, and if in small pots they may be shifted into a larger size as soon as the roots reach the sides, standing the pots on slate or tile shelves over hot-water pipes in preference to plunging them in bottom heat. If the eyes were inserted in pots or pans several together they may be placed in small pots singly, plunged in bottom heat, and when the roots reach the sides transfer them to 6-inch pots. Syringe well amongst them, and stop the laterals at the first joint.

Early Vines in Pots.—Top-dress with rich turfy loam and decayed manure in about equal parts, placing rims of zinc or turves round the tops of the pots, and when the roots are working freely in the top-dressing sprinkle a little fertiliser on the surface occasionally. Keep the laterals well in hand, avoiding crowding the trellis with foliage that cannot be fully exposed to light. Ventilate early in the day, affording a little air at 70°, increasing it with the heat to 85° or 90°. Avoid cold draughts, as they are prolific of rust, and impair the assimilating power of the foliage.

Early Forced Planted-out Vines.—The Vines started early in December must have the thinning of the berries attended to as soon as they are well set. Endeavour to obtain compact bunches, tying the shoulders in preference to cutting out a large number of berries. Remove superfluous bunches unflinchingly, striving for a full crop of well-furnished bunches, properly swelled, and perfect in colour and finish. Allow the laterals to extend beyond the bunches as far as is consistent with the exposure of the foliage to light, tying and stopping them as required. Afford a liberal supply of water or liquid manure as required to maintain the soil in a moist state, and mulch with an inch thickness of sweetened horse droppings. The night temperature may

range from 60° to 65°, 70° to 75° by day, with 10° to 15° advance from sun heat. Ventilate from 70°, and close between 80° and 85°, damping all surfaces well at the time. Do not syringe the foliage, as there is danger of sediment—a deposit on the berries.

Vines Started at the New Year.—Commence disbudding when the best shows for fruit can be determined, the object being to give the shoots left the benefit of full exposure to light and concentrate the forces on them. Allow at least two joints beyond the fruit in stopping, pinching laterals below the bunch to one joint, but those level with or above the fruit may be allowed to extend as space permits. When in flower afford a night temperature of 65° to 70°, with 10° to 15° rise from sun heat, closing at 80°. Vine flowers set best when the atmospheric moisture is not excessive. An over-moist, or, on the other hand, a dry atmosphere must be equally avoided. Muscats require a higher temperature and drier atmosphere than some varieties when setting, artificial impregnation being occasionally practised by fertilising every bunch with Black Hamburg pollen.

Late Grapes.—To do justice to late Vines they require a long season of growth, as to insure the Grapes keeping well they should be ripe by the middle of September. To effect this the Vines ought to be started at the end of the present month or early in March. Let the inside border be well supplied with water, and a supply of liquid manure will assist weakly Vines, but avoid making the soil sodden by needless applications. Remove loose surface soil from the border and supply fresh turfy loam with a little well decayed manure intermixed, sprinkling over each square yard 4 ozs. of approved fertiliser.

Late Houses of Black Hamburgs.—The Vines should be kept cool and the soil only moderately moist to preserve the roots in sound condition. It will be necessary to ventilate freely at and above 50°, and when that becomes the mean of the external air, or a little before, the Vines will break naturally. The Vines will set their crops by the early part of June, and the berries swell with sun heat, artificial heat only being required after the Grapes begin to colour.

THE KITCHEN GARDEN.

Broad Beans.—If extra early dishes are appreciated, a part of a warm border ought, where possible, to be devoted to the first crop. A moderately rich deeply cultivated soil suits this crop, and the seeds may be sown thinly in drills 2 inches deep and 2 feet apart. More seed may be sown in the open directly the ground is in a fit state, this crop forming a close succession to those in the warmer positions.

Peas.—Much that has been advanced concerning early Beans applies equally well to Peas. The extra early round-seeded varieties are the best to sow during the first fortnight in February, the wrinkled-seeded sorts frequently perishing if buried in cold wet soil. This important crop merits a good share of a south border, sowing the seed moderately thickly in wide drills 3 feet apart, or the rows may be disposed 10 feet or more asunder, the spaces between being cropped with Cauliflowers, Potatoes, or other early vegetables.

Peas for Planting Out.—The plan of sowing seeds in the open ground in November and nursing the plants through the winter has been superseded in favour of raising the requisite number of plants under glass, planting out when they are strong enough and the state of the weather permits. Extra early, if not particularly heavy crops are obtained in this way. For this purpose the early wrinkled-seeded varieties may be selected, and the seed may be sown either thickly in boxes, troughs, or 3-inch pots filled with fine soil, and placed in gentle heat to germinate, hardening before the plants are drawn, and planting out before the roots become badly matted together.

Peas in Frames.—If the required number of plants are raised in heat as advised, and turned out into pits or frames, a few early, if comparatively small, dishes may be the result. Brick pits or box frames are not indispensable, as it is possible to obtain equally as good crops in rough frames or pits with mats for protection. A mild bottom heat gives a good start to the Peas, and also to the rows of early Cabbage Lettuces planted midway between them.

Spinach.—Summer Spinach is usually associated with Peas, being grown in the spaces between the rows of the latter, the leaves reaching a suitable size for cooking before the Peas shade the ground. Sow the seed thinly in shallow drills midway between the rows of Peas each time sowings of these are made. Winter Spinach ought soon to commence growing strongly.

Potatoes.—It is yet early to commence Potato planting on a large scale, but exception may be made in favour of an early crop on a sunny border. Give the preference to short-topped, early maturing varieties, placing the sets about 9 inches apart in rows 20 inches or rather more asunder, in moderately rich, light, free-working soil. If the soil is at once ridged over the rows a good length of stem will be formed before the tops push through the soil. In any case a close look out should be kept for the latter occurrence, drawing soil up to and over the tops, or otherwise protecting them from frosts.

Garlic and Shallots.—Unless these are planted early their growing season is short. Rich, well-worked borders suit them. The divisions may be pressed into the soil, leaving the crowns showing through, disposing them 6 inches to 9 inches apart in rows 1 foot asunder. Underground Onions may be similarly treated. A little later Parsley plants, raised under glass, may be put out midway between the Garlic and Shallots, these not interfering with the progress and early maturation of these crops, and eventually occupying the whole of the ground.

THE BEE-KEEPER.

THE WEATHER.

OWING probably to the fact that the weather is an important factor in bee management, it is not surprising that bee-keepers are close observers of the various changes. At the time and place of writing a severe frost prevails; within the past twenty-four hours 22° of frost has been registered. The hives which are fully exposed are buried in snow, as are all the surroundings, to the depth of several inches. Many of the roads have been impassable owing to the snowdrifts, which are from 4 to 6 feet in depth. Although bad for travellers snow is an advantage in other respects, as it affords great protection to vegetation as well as to the bees in their hives. The cold spell of weather has been general throughout the country, but the snow only partially so, as a report to hand from a western county says, "Weather very severe, but little snow."

As long as the frost remains we allow the snow to remain on the hives, owing to the protection it gives to the inmates. But directly a change sets in it will be removed, as should there be any weak places in the roof the melted snow will soon find them out. After this takes place we shall probably have a few hours of bright sunshine, and it is then the hives will need attention, as with a rise of temperature the bees will be anxious for a flight after their confinement. We therefore repeat the advantage to be derived from shading the entrance. All that is required for this purpose is a piece of wood, tile, or slate placed in a slanting position across the front of the hive. It should be placed in such a manner that it obstructs the light but not the ventilation. The past two months have been a trying time for the bees, as January was showery and dull followed by extreme cold.

EXAMINATION OF COMBS.

There are many details in bee-keeping that lead on to successful bee management, which may be attended to at this season, when the bees require little attention. It is now a recognised fact that to be able to take due advantage of our short honey harvest spare combs are indispensable. To those who work largely for run or extracted honey it is their sheet anchor of success. We consider this point so valuable that we spare no trouble in keeping them in good condition. The system we adopt may bear repeating. After the honey harvest is over the combs are stored in a dry place; we prefer making a parcel of half a dozen, wrapping them in newspaper. They are then placed one on the top of the other in large packing cases. Before this takes place the box is loosely lined with some old shading material. This is well sprinkled with carbolic acid, which will have the effect of keeping out the wax moth, which is so disastrous to the combs. When the box is full similar material is placed over the top of the packages, the lid is closed, and treated thus a great number of combs may be kept in a small space.

It will be an advantage if combs stored in this manner are now examined. The paper coverings may be removed, and the combs brushed lightly to remove any debris. All should be removed from the boxes, or wherever they are stored. The material placed round the sides must be again sprinkled with carbolic, and the combs replaced in their former position. If this is done they will be ready for use, and be found in good condition when required. Such combs are also useful for the brood chamber, instead of using comb foundation when working for increase in the spring. It is not advisable to let the carbolic come in contact with the combs, and it is for this reason we wrap them in paper.—AN ENGLISH BEE-KEEPER.

TRADE CATALOGUES RECEIVED.

J. Potts, Rainford, Lancashire.—*Hard and Soft-wooded Plants.*

Rivoire père et fils, Lyons.—*Seeds and Plants.*

N. Smith & Son, Adrian, Michigan, U.S.A.—*Spring Trade List.*

Vilmorin, Andrieux & Cie, Quai de la Megisserie, Paris.—*Chrysanthemums and Dahlias.*

E. Webb & Sons, Wordsley, Stourbridge.—*Farm Seeds.*

- All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Pruning Ceanothus Gloire de Versailles (*Inquirer*).—It should be somewhat closely pruned in the spring, as it produces the flowers terminally or on the young growths. The young wood usually suffers more or less from severe frost, therefore it is necessary to reserve some well ripened wood of different lengths. Do not spur in all the growths, though this may be done when the plants have covered the space, cutting out the weak and leaving the sturdy well ripened shoots, spurring to a few joints of the old wood, and thinning the resultant growths so as to prevent overcrowding.

Stem of Gros Guillaume Grape Shrivelling (*Idem*).—It is not unusual for the bunch stem of this "Grape to shrivel whilst the Grapes still keep good," the shrinking being due to a sort of shanking after the berries are coloured and finished. Such occurs in many other varieties of a gross nature, and is probably due to the soft nature of the stem, commonly called unripe. There is no trace, as a rule, of disease in such parts, though fungal growths sometimes develop therein in a damp atmosphere.

Soil for Malmaison Carnations (*Novice*).—The exact proportions of the various ingredients used to form a suitable compost for these popular flowers must vary according to the character of the loam. If this is of medium texture containing a fair amount of fibre, incorporate with three parts of it one part of leaf soil sifted through a half-inch sieve, one part manure from a spent Mushroom bed, also sifted, one part burnt refuse with plenty of sharp sand and a little soot added. Should the loam be heavy, an extra part of leaf soil and a little pounded charcoal ought to be added. If, on the other hand, the loam is very light, dispense with the burnt refuse and use little sand.

Dressing for Tomato Border (*E. F. C.*).—The large growers do not continually keep planting the same border year after year in their large houses devoted to Tomatoes, but either occasionally remove the soil and bring in fresh, or grow the plants in pots stood on the old border. This is the practice of perhaps the largest grower of Tomatoes for the London market, and on the whole more satisfactory, especially as regards early crops and diseases, than growing in borders. It pays to make new borders; but as you say this, in your case, is quite out of the question, you may give the border a dressing of basic slag, 1 lb. per square yard and $\frac{1}{2}$ lb. of kainit, digging the dressing in with a fork, taking small spits, and working 10 to 12 inches in depth. If this were done now the conditions would be favourable for planting the Tomatoes after the bedding plants are cleared out. Then, before planting the Tomatoes, supply a dressing of mineral superphosphate, 34 per cent. soluble phosphate, three parts, and sulphate of ammonia one part, mixed, using 3 ozs. of the mixture per square yard, and mixing with the soil to a depth of 4 to 6 inches. If more vigour be required afterwards, the plants may be watered occasionally with nitrate of soda, not more than $\frac{1}{2}$ oz. to a gallon of water, and having it prepared some little time before use. It will hardly be required before the first trusses of fruit are set and advanced in swelling. Possibly the border would be all the better for top-dressing, after the plants are put out, with a little sweetened manure, not using more than about an inch in thickness. Of course, new loam on the top of the present border would be beneficial. One row of Tomatoes along the front of the house and

grown up under the roof would not generally give such good results as four well fruited rows about 3 feet apart. Still, when Mr. Doe of Knowsley had charge of the gardens at Rufford he had a crop from plants trained up the roof of a house that would have been difficult to excel by plants growing across the border. The roof plants were grown in a trough made of 11-inch deals arranged along the front. In one instance we knew of splendid crops of Tomatoes produced by plants in merchant's egg boxes which are only about 6 inches deep; but top-dressings of rich turfy soil were piled above the tops of the boxes and netted with a mass of roots, and judicious feeding was resorted to. The boxes were used because plants in the border were devoured by eelworms; those in the boxes were free. One grower is successful with one particular method, another grower with a different practice. We should imagine that any of the methods indicated would be better than planting in a border that had afforded standage for bedding plants through the winter.

Bulbs not Thriving (*P. Q. R.*).—The end of December is late for potting bulbs, many of which are much shrivelled at that time, and fail to grow. We should not have pressed the bulb into the soil "firmly," but should have made a cavity, resting each rather lightly than otherwise, on a very sandy base. With the soil moderately moist at the time, but not decidedly wet, and the pots plunged in and covered with damp ashes, we should expect that roots would form if the bulbs were not exhausted. They would not form and take possession of dry soil, while, if the ashes were dry also, these would absorb moisture from them instead of, what is needed, imparting it to them. If the soil in the pots is very dry, give water at once, and if it does not enter freely, stand the pots half their depth in water, leaving them there for an hour, or until the moisture rises through to the surface, then plunge them to the rims in damp ashes and invert some small flower pots over the crowns. If they do not grow under that treatment they will not grow at all. If you can maintain regular moisture in the soil without plunging, that will answer equally well; but very few amateurs can accomplish this, and the plunging system is the safest and best.

Point Judging (*S. E. H.*).—When there are a great number of items in a class, as is of necessity the case in judging gardens and allotments, there is no method comparable to that of determining the value of each article and recording it in points or marks. The same system is necessary in close competitions with blooms of Chrysanthemums, Roses, and other flowers, also for dessert tables, as well as collections of vegetables and fruit. It is based on the fixture of a maximum value for each item, and from that working downwards as may be necessary, and entering the value of the several items examined. For instance, if 8 marks are agreed upon as a maximum for a crop of Onions, or anything else, and the judges should only consider the crop half good they would give it 4 marks, if $\frac{3}{4}$ good 6 marks, if $\frac{1}{2}$ good 2 marks, or set down anything between those figures as more clearly representing actual merit. Maximum marks vary according to the value or difficulty in producing the products to which they are attached. If you send 3d. in stamps to the publisher, and ask him to send you the *Journal of Horticulture* of August 31st, 1899, you will see a record of marks allowed for the several items in the great dinner-table class at Shrewsbury, also those actually awarded by the judges. A mistake very liable to be made by adjudicators who have had little or no experience in this method of judging is to commence pointing too high. They might easily give the full allowable number of marks to the first Onion bed examined, and then in the next garden find a better. They are then apt to feel rather sheepish, and certainly not like the cautious judges they ought to be. Maximum marks are only justifiable by products regarded as *unsurpassable*, and these are few in these days of high competitive cultivation.

Canadian Wonder Beans Diseased (*Subscriber*).—The plants have been carefully examined and found to be infested by a parasitic fungus, which produces in the root-stem what is known to cultivators as "rust" or "canker," and the effect on the leaves and pods is called "leaf-spot" or "pod-spot," just as the parts respectively are infected. It has also received the name of anthracnose, while the organism itself has been called *Colletotrichum lagenarium* by some authorities, and by others *Glaeosporium Lindemuthianum*. The disease is seldom destructive, except during seasons of cold rainy weather, though very common in several European countries, and has been found over a large portion of the United States. The parasite thrives, as before stated, in cold rainy weather, and under glass when the plants are kept too wet at the roots in a low temperature, and the atmosphere saturated. You are right—a chill, such as watering in cold weather—would help the fungus and induce that condition favourable to its development. When the plants are kept in a rather high temperature and somewhat dry atmosphere, water being given sparingly at the roots, the disease makes little headway. Planting in a light soil, on high, well-drained land, is one of the best preventives outdoors, and these conditions apply equally to plants under glass—namely, a temperature of 60° to 65° at night, and 70° to 75° by day with sun heat. Lose no opportunity to admit air, exposing the plants to all the light possible, and be careful not to have the soil very wet. As the disease goes over in part with the seeds, it is well to examine them before sowing and reject all that show evidence of the malady. From some experiments we have made good results attend soaking the Beans before sowing in a solution of blue vitriol, 1 part in 12½ parts water, for ten minutes.

Raising Tomato Plants for Houses and Outdoors (Beginner).—The plants may be raised readily in frames over hotbeds, the seeds being sown in pots, pans, or boxes, commonly called propagating trays, being 15 inches long, 9 inches wide, and 2 inches deep. The proposed roughly constructed pit will answer for the plants after potting just as well as the most costly structure, and it need only be so high at the sides as to allow of a flap a board wide, for ventilation, about 18 inches from the ground, so that the sides need not be more than 2 feet 6 inches high, or even less. The roof should be span, so that the plants may have light from all sides, it not being possible to have them too sturdy, and they get more light in a span, and are nearer the glass than in a lean-to. Besides, the back of a lean-to will require to be a considerable height to allow for head room. A structure about 12 feet wide, 2 to 2 feet 6 inches high at the sides, and with 7 feet 6 inch roof-lights, and ventilators along the ridge, would be suitable. It should have a flow and return 4-inch hot-water pipe on each side, and include provision for plenty of air, as there is little chance of good results without securing sturdy plants. The house so constructed would always be useful, and cost very little more than the makeshift; indeed, the proposed one is inadequate to the requirements. No unheated structure would answer for Tomatoes by the 1st of April, and paraffin stoves are out of the question, as the structure must be such as to bring the plants on, even for planting outdoors, otherwise good results cannot be looked for. The raising of the plants is a very important matter, they being thinly grown from the start. The cheapest effective covering is scrim canvas, but even this is of no use without hot-water pipes, for frosts are sometimes very severe in April. The end of March is a good time for sowing to raise plants for outdoor planting, but it is necessary that they be grown well, hard, strong, and showing the trusses of bloom when planted out in May, or as soon as safe.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (F. C.).—1, *Lindleyanum mirandum* (Odontoglossum mirandum of Reichenbach); 2, *Dendrobium luteolum*. (A. L.).—1, *Dendrobium primulinum*; 2, *Vanda gigantea*; 3, *V. Amesiana*; 4, a pretty white form of *Laelia anceps*; it is of no value in its present state, but might develop into an excellent variety under the best cultivation. (H. J. T.).—1, *Adiantum pubescens*; 2, *Phoenix dactylifera*; 3, *Selaginella caesia*; 4, *Iris tuberosa*, the Snake's-head Iris. (C. R.).—1, *Cypripedium Spicerianum*; 2, *C. insigne*; 3, *Dendrobium Wardianum*; 4, *Adiantum formosum*; 5, *A. Pacotti*; 6, *Scolopendrium vulgare cristatum*. (D. S.).—1, A poor form of *Odontoglossum crispum*; 2, *Cypripedium insigne*.

SPRING CLEANING FOR THE YOUNG.

WE are in terrible fear—not of our Editor, oh, no, nor of our general readers—they would smile and say nothing. But what of the ladies of the family? Do they ever read “Home Farm?” Not unless there is something that appeals to them. We hope they will not see this number, at least those of them who have reached maturity. They might scoff, at any rate they would sneer, “What has a mere man to say about cleaning that we do not know far better than he?” Oh, yes, we quite agree, humbly assuring them that we would never enter into argument with them, but we are thinking now of the young folk, those who will occupy our places in a few years and do things better than we have done them. But the young are forgetful; their minds, perhaps, are not altogether “on pleasure bent,” but they are apt to slip little minutiae, thinking that such trivial matters are of no moment.

We are not speaking of house cleaning, that is not our province, but of the dairy and the utensils appertaining thereto we would write. Just now in the generality of farm houses dairy work is slack and has been during the winter months, but every day now cows will be falling due to calve, and will greatly be on the increase. Some dairies are light and airy and not too big, still during the short and cold days it is quite possible that the daily cleaning may have been a bit slipped. It is not pleasant to be rubbing and scrubbing stone shelves and cemented floors in a low temperature and by the aid of candle or lamp—in fact it is impossible with artificial light, or even the best light afforded by a December day, to rout out all the corners or crannies. For one thing the water, however hot, cools so quickly, and for dairy work hot water is an essential. Happy is that dairymaid who has a nice cemented floor and slate or stone shelves; her diffi-

culties are nil compared to her neighbour who may have a badly laid brick floor and old wooden (and possibly worm-eaten shelves). Oh, yes, dairies of that sort still exist, and there are others that in a wet time flood. The tenant has not the means and the landlord not the will to alter this state of affairs.

We read in books how delicious is the sweet smell of fresh milk. So it may be, but a dairy wants to be perfectly odourless. This can be done if the presiding genius is of modern culture and fully alive to her responsibilities. There is an earnest desire now on the part of those who have taken up dairy work to aim at the highest degree of perfection, and perfection without cleanliness is unattainable. We do not speak of dairies with tiled walls, where no atom of dirt can lodge, but just of simple homely places that owe their whiteness to lime. Nothing beats lime, but lime accumulates, and though a woman would never hesitate about dispapering a room before the new one is hung, yet it may never occur to her that the walls would be better for a good scraping and washing. Those walls—we speak from our own knowledge—are by no means even. There is many a rough ledge or cranny where the lime has lodged year after year. A garden hoe does not make a bad scraper, and a rough besom and hot water will prepare a nice wholesome surface for the new wash. There may be painting of doors or woodwork round the windows. Best do it now and get off the smell of paint before the milk pans are all full.

There is one little item has often struck us. The window may be, and probably is, covered with wire or perforated zinc. Is that ever moved, year in, year out, to give the window a chance of a thorough cleansing? We have seen windows and wire that have stood untouched for many a long season. This is only a small matter, but bacilli lurk everywhere. The light we know is bad for them, but the zinc is not very transparent. Surely in no dairy worth naming is a drain opening. We have read of such things, we have heard of such things, but only, we hope, in fiction. All superfluous moisture should be taken up with floor flannels; if the ventilation is good Nature soon makes all dry. It is a mistaken idea a damp dairy.

Now as to utensils; what of them? The separator has had a winter's rest. Has its abode been dry, or is there in any part an atom of rust? What about the various workings? Remember the time is at hand when it will be needed to deal with large quantities of milk twice daily. Just look it over carefully, and thus guard against a breakdown at an inconvenient moment. What of the larger churn, the one for summer use? Has it ever been looked to since the autumn? Remember wood is apt to get "fusty." Take it out into the fresh air, and give it a thorough hot scrubbing. Perhaps, too, there may be a trifling repair needed. As to the pails, we suppose they are shining like silver, and hung up out of the way. How beautiful the old wooden ones were when fresh scoured, with the steel bands burnished to a radiancy. They were heavy and perhaps clumsy, but certainly more picturesque than the tin ones, and we fancy sweeter and cleaner.

All wooden utensils should be seen to—bowls, butter workers, Scotch hauls. If they have been kept dry all the winter there will be shrinkage, and they are all the better for a good soaking and overhauling. We do not like cream panchions or milk bowls that are a bit chipped or cracked; they are not good to clean, and will soon breed nastiness. The housewife is always glad of an extra bowl or panchion, and it is economy to get new whole articles. Most farms possess a wooden rack for panchions and pails to "sweeten" in during the day. It may need a coat of paint or be loose in a joint.

Butter cloths have happily gone out of favour. We never did like them; we could always fancy they had a "flavour." The parchment paper which has taken their place is both cheap and excellent. But the paper does not answer for cheese binding and making, and during the long winter evenings young hands might find excellent employment in hemming new cloths, so that there should be no lack when the busy time came. Unhemmed cloths do not look workmanlike; raw edges are always untidy. This is a small matter, but one worth mentioning. Where cheese is

made spring cleaning is even a more serious business—there are so many vessels to see to and storage rooms to purify.

Need we again say that the dairy should be a temple devoted only to the keeping and safeguarding of milk and milk products? It is cool and tempting—such a thorough draught that meat would hang indefinitely, and other comestibles preserve their virtues for long; but the housewife must be inexorable. She never knows how easily a taint may come. It is in her power to keep clear, and it must be a case of milk or nothing. She might as well give up her work as to allow of any profanation of her temple.

We hope we have offended no one, that is far from our intention; we only want to save our fair workers difficulty and disappointment for the future. We wish their butter and cheese to "top" the market, and to fill their pockets with shining gold pieces.

WORK ON THE HOME FARM.

Frost and snow! Heavy snowfall and keen frosts, registering as low as 7° Fahr., or 25° of frost. And this in mid-February! In some seasons we might have rejoiced in such a visitation, for with plenty of stored roots the stock breeder and feeder could ignore such weather, or rather rejoice that his arable land, whether for spring corn or Turnips, was getting such a preparation for seedtime as he could not give it. But now! Turnips and Swedes are all finished, and the scanty supply of Mangold all that is left to assist the straw and hay to keep sheep and cattle alive until the grass begins to grow.

No work on the land has been done since last week. Muck leading is the only available work, and that will soon be finished for the present. Employment may be found for a few days in carting bricks for building repairs and pipes for draining, then the horses must rest if the frost lasts. A rest will do them no harm, but they must be judiciously fed; after the first day the corn allowance must be reduced at least one half, and the linseed porridge tub must not be neglected. Work may be found for the men in whitewashing the stables and cowhouses; a good limewash never hurts anything, and if a small quantity of phenyle be mixed with it its disinfecting properties will be improved. Straw is now so plentiful and cheap that the use of peat moss litter may be neglected, to the detriment of the farmer. Having thoroughly tried the litter we are convinced that, although straw may be, and is, far preferable as bedding for the comfort of the animal, there are great manurial advantages in the use of peat moss. A 3-inch layer on the floor of every box and shed will absorb a large quantity of valuable ammonia, which would otherwise be lost.

Basic slag may now be bought, and would be better on the land than in the shed, but if it can be procured and placed upon the premises a job may be found for the horses. Kainit also might be got, and would be more useful if applied at once. The sowing of these manures is not pleasant work in wintry weather, but work must be done some time, and a great deal of it is unpleasant at any time. Sheep are doing well on short commons, and lambs are healthy, but the cake bill will be a heavy one. Will they pay for it?

SCARCITY OF FARM LABOUR IN THE STATES.—Reports from the West and South state that there is a lack of labour in the farming districts. The farmers always complain about this time of the year of scarcity of hands, but in previous years it has not been as serious as it is now. Not only are more men needed than usual because of the excellence of all the crops, but it is impossible to obtain the average number of labourers. The present condition has been brought about principally by the large orders received by factories and mills in what is ordinarily their dull season, and the ability of labourers to find work at home without wandering away in search of it. The farmers are offering double the wages usually given, and this is attracting men from poorer positions.—("Yorkshire Post.")

CALF MEALS.—After extended trials among farmers in various districts and unknown to each other, we are able to announce a consensus of opinion in favour of the following calf meal or milk substitute:—

Finely ground linseed	8 lbs.
Barley meal	13 lb.
Wheat meal	14 lbs.
Carbonate of soda	3 ozs.

This should be mixed with a little cold water, so as to make it of a thick creamy consistence, and the boiling water added, stirred for a few minutes, and given when new-milk warm. By finely ground linseed is meant the fine linseedmeal formerly sold for poulticing, but since superseded by crushed seeds which contain the oil. We do not want the oil in this case, as young calves cannot emulsify it in the stomach and intestines, and failing to do that it would cause scouring. Wheatmeal, of course, means whole wheat, not flour. This mixture answers well without the carbonate of soda, but with it there are fewer reports of scouring, and we give the soda the credit of preventing that acidity which is often the forerunner of skit. Where the distressful malady persistently recurs (and it does on some lands) the amount of soda may be doubled for a while.—("Farmer and Stock Breeder.")

BARR'S SEEDS

OF FINEST SELECTED STRAINS AND TESTED GROWTH

NOVELTIES & SPECIALITIES FOR 1900.

Barr's Golden Wax-Pod Dwarf Butter Bean; the fleshy pale yellow pods run to Sin. long, are stringless, and of delicate flavour; it is a marvellous cropper and very early. Per pint, 1/9; per quart, 3/6.

Barr's Lightning Runner Bean, a remarkably prolific Runner, and the earliest of all, bearing numerous heavy clusters of long fleshy pods of a fine delicate flavour; a valuable acquisition. Per quart, 2/6.

Barr's Covent Garden Beet, dark crimson flesh, fine flavour, medium size. Per packet 6d.; per oz., 1/3.

Barr's Hardy Winter White Broccoli, a magnificent Broccoli; should be sown from end of March to May for a succession. Per packet, 1/-; per oz., 2/6.

Barr's Little Queen Cabbage, of delicate flavour; highly recommended. Per packet, 6d.; per oz., 1/6.

Barr's New Intermediate Carrot, superior medium long Carrot, of a rich red colour and fine cooking properties. Per packet, 4d.; per oz., 10d.

Barr's Champion Solid White Celery, solid and sweet, remaining long in condition. Per packet, 1/- and 2/6.

Barr's Paragon Cabbage Lettuce, light green, leaves smooth and succulent, medium size, all heart, sweet and tender. Per packet, 1/-; per oz., 2/6.

Barr's Scarlet Perfection Radish, an extra-fine, very early, short-topped, turnip-shaped Radish; colour, rich scarlet; flesh white, mild, and crisp. Per oz., 8d.

Barr's Early Ruby Tomato, solid, deep-red fruit of fine form and medium size, abundant cropper and very early. Per packet, 1/-.

BARR'S SEED GUIDE contains a Select List of the best Vegetables and the most beautiful Flowers for Garden and Greenhouse. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. Sent free on application.

BARR & SONS, 12 & 13, KING STREET,
Nurseries: LONG DITTON, SURREY.

PHLOXES, PENTSTEMONS, ANTIRRHINUMS
For the best, most accurate, and most reliable information about these and all other GARDEN FLOWERS, see **FORBES' ILLUSTRATED CATALOGUE**, 152 pages, for 1900, free on application.

JOHN FORBES, Nurseryman, HAWICK, SCOTLAND.

ALL WHO WISH GRAND RESULTS should use **THOMSON'S IMPROVED VINE, PLANT and VEGETABLE MANURE**. This valuable Manure is yearly growing in public favour. Can be had of all Nursery and Seedsmen, or direct from the makers, **WM. THOMSON and SONS, Ltd.**, Tweed Vineyard, Clovenfords, Galashiels, N.B. Price Lists and Testimonials on Application. 1 cwt. and upwards Carriage Paid to all stations in Britain and Ireland. London Agent—**Mr. J. GEORGE**, 14, Redgrave Road, Putney. Agent for Channel Islands—**Mr. J. H. PARSONS**, Market Place, Guernsey. Also **THOMSON'S SPECIAL CHRYSANTHEMUM MANURE**. ½ cwt. Carriage Paid to all Stations in Britain and Ireland.

COTTAGE GARDENING; being an Essay to which the Royal Horticultural Society awarded Mr. W. EGERTON HUBBARD'S Prize, February 16th, 1870. By E. W. BADGER. Third Edition. Price 3d.; post free, 3½d. Office: 12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

HEATING APPARATUS for Greenhouses and other Buildings. Catalogue free of all kinds of Hot Water Pipes, Wrought and Cast Iron Boilers, Radiators, Cisterns, Pumps, Baths, &c.—**JONES & ATTWOOD**, Stourbridge.

PURE WOOD CHARCOAL, Specially Prepared for Horticultural use. Extract from the *Journal of Horticulture*: "Charcoal is invaluable as a manurial agent; each little piece is a pantry full of the good things of this life. There is no cultivated plant which is not benefited by having Charcoal applied to the soil in which it is rooted." Apply for Pamphlet and Prices to the Manufacturers—**HIRST, BROOKE & HIRST, Ltd.**, Leeds

VINE CULTURE UNDER GLASS—By J. R. PEARSON, The Nurseries, Chilwall, near Nottingham. Price 1/-; post free, 1/1. Fifth Edition. Office: 12, MITRE COURT CHAMBERS, FLEET STREET, E.C.

GREENHOUSES from £3 5/-; VINERIES, CONSERVATORIES, FRAMES, SUMMER HOUSES, &c. Illustrated List Free. Makers to H.M. THE QUEEN and H.R.H. THE PRINCE OF WALES.

THE SWEET PEA BICENTENARY.

GREAT SWEET PEA SHOW,

AT THE

Crystal Palace, July 13 & 14, 1900,

We shall offer Four Prizes amounting to £25,

VIZ.:

FIRST PRIZE	£10 0 0
SECOND	7 0 0
THIRD	5 0 0
FOURTH	3 0 0

For 100 Bunches of SWEET PEAS, consisting of the following Shades of Colour:

Dark Blue	Carmine and White
Sky Blue	Pink and Rose
Rich Purple	Scarlet, striped
Blue and Purple, striped	Primrose Yellow
Brilliant Scarlet	White

Open to Amateurs and Gentlemen's Gardeners only.

Full particulars and Schedule can be obtained from Mr. R. DEAN, 42, Ranelagh Road, Ealing, W.

Sutton's Sons

THE ROYAL SEED ESTABLISHMENT, READING.

Special Exhibition Collection of Seeds of Sutton's Giant-flowered Strain of SWEET PEAS, consisting of the 10 shades named above, 7/6.

WEST'S PATENT GARDEN SPECIALITIES.

WEST'S PATENT Vapourising Fumigator

Best and Cheapest, for being made of brass and zinc will last for years. The stove only requires a little spirits to saturate the asbestos, so may be used thousands of times without wick or further trouble than filling it. Price 6d. complete to vaporise up to 2500 cubic ft.

"WEST'S EXTRACT OF NICOTINE," is guaranteed pure Nicotine and is even cheaper than the compounds that are only chemical substitutes for Nicotine (compare prices), 7d. per air-tight sealed bottle of 1000 cubic ft.

"SUNPROOF" SHADING in 6d. lb. tins ready for use, to be mixed with cold water. Guaranteed to be perfect in all respects and the cheapest shading that can be made.

For particulars of West's patent "Ivory" Plant Labels, Soft Metal Tree Fasteners, S.M. Clips, Wall Nails, Plant Stake Grips, Plant Pot Crocks, Insecticides, Fertilisers, Canes, Sticks, and ALL GARDEN SUNDRIES of every description see Illustrated Catalogue, post free.

Samples free, postage for samples and goods extra. All goods made on the premises by C. E. West, so send direct to the Manufacturers.

Gratis, "Orchid Culture," 3rd Edition, postage 2d.

Gives full particulars of the cultivation of Orchids. THE LEEDS ORCHID COMPANY, ROUNDHAY, LEEDS

Journal of Horticulture.

THURSDAY, MARCH 1, 1900.

The Journal of Horticulture can be obtained from the Office, 12, Mitre Court Chambers, Fleet St., London, post free for a Quarter, 3/9. Editorial communications must be addressed to 12, Mitre Court Chambers, Fleet Street, London.

MANAGEMENT.

EARLY training, whether acquired from others or elaborated by oneself, exerts an influence beyond expression on one's future. The man who is started on correct lines at the beginning of his career, and who continues to train himself—to educate himself—possesses a reserve force equal to meeting most emergencies, and gives him a power in the discharge of ordinary duties that renders them light and pleasant. The practice of thinking out methods for oneself is one to which all young men ought to accustom themselves; I mean not to accept lessons in routine, no matter of what nature—digging, pruning, or training—without digesting the matter in their own minds, and the outcome will be not only a more intelligent grasp of the particular practice, but almost certainly some original modification of it to suit circumstances when they arise. We all know people who have so nicely adjusted themselves to grooves that the addition of some extra work, without a corresponding contribution of labour force, causes a complete dislocation of arrangements. The reduction of their working force acts in exactly the same manner. There are others who have acquired an elasticity in managing both men and work who are unaffected with such changes, and who cause one to wonder how so much "ground" can be got over so successfully. The one is certain to be a man who thinks for himself; the other acts on the thoughts of other people and possesses no power of initiative.

There are some points of management that one and all must follow to be successful. The accomplishment of routine work at the proper time is one instance of which systematic hoeing may be taken as affording a happy illustration. The result of this practice is the absence of any except seedling weeds of the smallest dimensions. No time is lost in the performance of the work which always occurs when weeds have gained strength. The work is of better quality, for, carried out with care, scarcely any weeds will be left to grow, which cannot be said to follow hoeing when weeds are strong. The labour thus saved is time gained to overtake other work, and finally its effect is cumulative, because all garden labour performed at the

No. 2683.—VOL. CII., OLD SERIES.

proper time is quicker of accomplishment than if postponed. It is quite a common custom to leave certain work, such for example as Box trimming, to the second or third year in order to save labour. As a matter of fact the practice is followed by an increase of labour. A properly kept edging demanding annually little attention in comparison with that which has gone wild for two years.

In no part of outdoor gardening is the value of system more apparent than in the care of flowers in borders or in beds. It is very generally thought that the only method possible to pursue in order to furnish borders to overflowing, and to allow the plants to fill every inch of space, is to leave them to themselves. To do so is, however, to court defeat, and to increase labour afterwards trying to put matters right. I have followed a systematic method of examining all outdoor arrangements at short intervals, with the result that the end in view has been secured with an expenditure of the minimum of labour, and the flowers themselves to ordinary appearances exhibit no signs of having been touched. When allowed to grow practically wild it becomes, long before the end of the season, a struggle for existence with the plants, and no end of work, unsatisfactory at the best, to render things less chaotic. My first lesson as to the value of oft repeated attention to flowers was derived from a clever suburban gardener, who at the time when carpet bedding was at the zenith of popularity produced perfect examples of that style. I remarked to him on the labour involved in keeping in such perfect order so many beds and borders as he had in his care, and he assured me that he himself overtook all the labour, which was confined to two hours weekly on one morning before breakfast.

One of my cares is to impress on young men the immense amount of labour they would save themselves by sponging or otherwise cleansing plants which are subject to insect infection, but few of them spontaneously attend to this necessary work, but must be specially instructed to do it.

The above are instances illustrative of methods at once rapid in execution, and resulting in the best effects. There are, however, other routine practices which may be too quickly done to yield ultimate satisfaction. A common case is that of digging—one of the ordinary operations of gardening that is becoming a lost art. With scarcely an exception, young men in carrying out this important work insert the spade at an angle, turn the soil upside down, and then proceed to do the same with the next spadeful. I admit that this method permits a garden to be got over in a shorter space of time than by the older way of inserting the tool as nearly as possible perpendicularly, and finishing the operation by smashing any clods in the furrow. The latter method, however, repays itself by a deeper soil, better cultivated, less affected by weather, and certainly more fertile—the very reason for the operation.

One of the greatest aids to the smooth running of a garden is the capacity to determine the most suitable time for performing work; and on the other hand, when it is possible to diverge from cut-and-dry practices. Sowing and planting at the times best suited for particular crops are most important, and much time may be lost in rectifying mistakes of this nature. Such, for example, as sowing winter crops so early as to require an intermediate transplanting; or in the case of flowers, such as Asters, Marigolds or Stocks, making a mistake of the same nature, with consequent pricking-out and attention, that sowing at a later date would have rendered unnecessary.

In the same way one may often diverge considerably from the beaten track if ultimately the result shall work out equally well. In this way shrubberies, hedges, and edgings may often be managed successfully by working them up at odd times when other work cannot be carried out. Even that all-important operation, the planting of the summer flower garden, an incubus to many hard-working men, loses much of its terror if, instead of attacking it with all forces till it is overcome, we take it in detail and as plants are ready, the harder first; we select suitable opportunities, a day, or even half a day, at a time, extending over several weeks, till all are in place. This method, while it lessens—nay, dissipates—worry, allows us to carry forward other necessary work as well, without causing neglect to the flowers.

Perhaps, however, the greatest source of waste, or, on the other hand, of working force, is the management of workmen. Scarcely any workman possesses adaptability, or, in popular parlance, sees an inch before his nose. Hence arises the necessity of the head to be constantly watchful that the proper men are detailed to particular jobs, that rapid or perfect methods are adopted, and suitable numbers to carry out an operation are selected. Jethro Tull's opinion that all workmen were rogues at labour is incorrect. Generally they take a pleasure in work if it is interesting, and to most men it is possible to impart a feeling of interest by getting him to think he is occupied in an important operation, and that you expect him to carry it out well and effectively.—B.

BUD-DROPPING IN PEACHES.

In some seasons there is much trouble given by the wholesale dropping of the buds of Peach and Nectarine trees at the time when the sap becomes active and the consequent swelling of the bud commences. This, of course, varies with the forced and natural growth of the trees, but bud-dropping is sometimes known in each case. Last summer and autumn was of such a tropical nature that there was often a shortness of water, and the trees suffered from the restricted supply, as it was impossible to give the usual periodical soakings. This was so in my case, and I should not have been surprised had bud-casting become a prominent failing this year, when on the verge of starting into bud-growth. It is therefore gratifying to find that such anticipations are not being realised, for both early, mid-season, and late trees showed little tendency to do this, or, at any rate, not more than happens in ordinary seasons.

The season was remarkable for the extent of drought and its effect on vegetation generally, and Peach trees, both indoors and on open walls, suffered more or less in accordance with the facilities afforded the garden in its water supply. There were cases where almost every drop used had to be carted from some distant spring, and to expect that a large extent of fruit houses and outdoor trees could be given their usual supply would be as unreasonable as it would be impossible, when so many other demands are made on the supply available. Some seasons when there is a continued spell of tropical summer weather the earlier trees become what is termed over-matured, and this has been set down as a cause for the premature fall of the buds in the early spring.

Such experiences and results tend to overthrow the views one is inclined to take up, and explode little theories that gather in the mind. There must be reasons for such erratic actions on the part of trees, but to the average gardener they are not easy of solution. In my own case I felt certain that trouble was in store from the knowledge of the fact that a diminished water supply at a critical time is ordinarily the precursor of bud-dropping in due season. There were in last year all the needful attributes for bringing about this undesired failing, which make one ask the question why is it not so? There must have been something sustaining them. In older trees the roots penetrating deeply into the border would be some help; but what of the spider-infested foliage? These destroyers of healthy leafage were much in evidence last summer, and were with much difficulty held in check, and too often the early fall of the leaf was an inevitable result of their presence.

Herein was found another reason for expected trouble, which, happily, has not been realised; and why? Is it because their principal functions were complete early, or did the late autumn watering make good their earlier deficiencies even without leaves. The case gives rise to deeper thought the more one dwells upon it, but it might prove a fatal mistake to rely on the experience gained and to relax one's efforts in future seasons by reason of favourable results gained in the face of such unintelligible elements. It would be interesting if other readers gave their experience bearing on the prospects of the buds following such a trying season as that of 1899, when there was a dearth of water and a wealth of red spider.—W. S.

ONCIDIUM CRISPUM GRANDIFLORUM.

YES; "R. J. H.," there is an *Oncidium crispum grandiflorum*, and your supposition that it should be *Odontoglossum crispum grandiflorum* is an erroneous one. This *Oncidium* was placed before the Royal Horticultural Society upwards of ten years ago, when it was awarded a first-class certificate by the Orchid Committee. The flowers (fig. 44) were of great size, over 3 inches in diameter; the sepals and petals deep brown, with some yellow markings, the base of the lip having a broad rich yellow band. It was exhibited by Mr. J. Charlesworth, of Heaton, Yorks.

ONCIDIUM SPILOPTERUM.

THIS species is well worth growing on account of its very bright and showy appearance when in flower, the fine chrome yellow tint of the segments being unsurpassed in the genus. Anyone having an intermediate house a little warmer than where the coolest section of *Odontoglossums* thrive will be able to grow it to perfection, and a suitable compost will be found in equal parts peat and moss, with a few pieces of broken charcoal and crocks. The pots must be of medium size only, and water in small quantities only is required. A native of large tracts of country in South America, it naturally varies a good deal, but all the forms are effective.

CATTLEYA SCHRÖDERÆ.

To many people the idea that one form of *C. labiata* is better than another seems absurd, but for beauty I am doubtful if there is one to beat *C. Schröderæ*. Its charm lies in the beautifully crisped petals and lip, and in that delicate heliotrope-like odour always noticed in a house wherein it may be flowering. There are several varieties of it, one especially pretty form having pale mauve sepals and petals, with a rather deeper lip covered partly with a deep orange yellow blotch. There is also a white form, but it is not the best of the albinos by any means, as it lacks that snowy whiteness so characteristic of some of the others, such as *C. Mossiæ Wagneri*.

For cultural purposes group it with *C. Trianae*, of which some authorities make it a variety, and allow it a light airy position with the Brazilian species generally. During the early months of the

FIG. 44.—ONCIDIUM CRISPUM GRANDIFLORUM.

year it is quite possible to overwater this species, and a frequent mistake made in its culture is overdrying the roots in winter. It likes a good supply of water when growth and roots are both active, and a

little extra warmth in early spring is advisable. For compost use the ordinary peat and moss mixture, giving good drainage and pots of medium size.

TRICHOCENTRUM ALBO-PURPUREUM.

Though not a showy Orchid, this is very interesting and pretty, and a few plants may be grown where a variety is liked. The flowers (fig. 45) are small, have brownish and green sepals and a white lip with a purple spot on each side of the crest. A native of Brazil, it should be allowed a fair amount of heat and moisture; but the plant is too small for growing in large pots, and the most likely plan to

FIG. 45.—TRICHOCENTRUM ALBO-PURPUREUM.

succeed with it is placing the plants upon soft blocks of Tree Fern stem with a little moss about their roots, though some growers succeed with it in pans. A fair amount of moisture all the year round is better than very widely divergent treatment summer and winter.

CYMBIDIUM DEVONIANUM.

A well-flowered plant of this species with its pendulous spikes of blossom, each one a study in browns, is very interesting and pretty, but, unfortunately, it is much too rarely seen. I noted a fine specimen with ten spikes during the week, and though flowering earlier than usual was none the less welcome. Its best position is suspended in a basket near the roof, and though many cultivators still keep it in a hothouse the specimen above referred to was grown in a cool temperature. Ample moisture and a substantial compost are needed.

LÆLIA JONGHEANA.

This being the season when the flowers of this *Lælia* may be expected those having plants from the recent importation will have an interesting flower to look forward to, and, unlike most kinds, one which the majority of growers have not seen. It will never probably gain any very important place, but it will be useful for hybridising, and possibly good forms of it may turn up. Although so rare before the discovery lately, it is interesting to note that it has been known for just upon half a century, having been discovered in 1854. Then it was probably lost sight of for a number of years.—H. R. R.

SPRING POTTING.

RENEWED interest appears to spring up in the mind of the cultivator when several healthy rooted cuttings are ready for their first potting. It may be that the cuttings were inserted singly in small pots, which they have now filled with pushing rootlets that are seeking fresh feeding ground; and if they should remain long in these pots the growth will be weaker than is desirable, hence these small plants require attention first. Rooting cuttings round the edges of 3-inch pots is a common and ready method of securing a good stock, as the cuttings often root more freely in this position than they do in the centre of a mass of soil in smaller pots. Both methods are good, and with care successful rooting follows, and little check is given in the potting. Numbers of cuttings are also rooted in shallow boxes and beds. All, however, should be placed in pots when sufficiently rooted, and before the roots mat themselves together or the top growth elongates.

As a rule the best size of pot for the first potting is a 3-inch. That the receptacles should be clean and dry is essential. The crocks employed as drainage material must also be in the same condition. The compost ought to be previously prepared, and in the condition of being neither wet nor dry. Well decayed fibrous loam, carefully pulled into small pieces with the hand, should form the base of the compost. Two parts of loam to one of leaf soil will form a suitable compost, adding a moderate proportion of sharp sand. If the loam be of a heavy character, the addition of crushed charcoal will tend to insure its porosity. A very rich and elaborate soil is not necessary at first. It is more desirable that the growth should be stocky and short jointed, even if it is longer in being produced, than to be run up quickly.

Arrange the drainage in the pots carefully so that little suffices, and cover with some of the turfy parts of the compost. Cuttings rooted in 2½-inch pots can scarcely be accommodated in the 3-inch size, therefore provide for them 4-inch pots. When several cuttings are in one pot they will turn out better when well rooted, and can be divided readily without the soil falling away from the roots. All cuttings do not root alike. Some are rather slow in the process, and it may be found necessary to divide and pot them while yet they have few roots. The soil frequently does not adhere to these, but falls away, hence the roots must be placed directly into fresh compost, which they frequently take to readily. Before placing the plants in the pots, introduce a little compost over the drainage, on which place the plants and carefully lay out the roots in it which are free and loose. Fill in more soil, then shake the whole down by a few knocks or jars on the bench. This will usually fix the plants and the soil firmly enough for the first potting.

The best position for the newly potted plants is a frame, arranging them on a bed of ashes, which must be kept moist, and the plants not far from the glass. Water may not be required for a few days if the soil was moist when potting, but should the weather be bright syringe the plants early in the afternoon, and keep a little close at first, simply to encourage fresh root action. The close confinement must not be carried on too long: immediately it is seen that new growth is commencing afford more air. Give water as required, keeping an eye on the plants on breezy sunny days, as the soil is then liable to dry quickly. Frosty nights often occur during March, and with the plants close to the glass they may suffer if this is not protected at nights. A single thickness of dry matting will keep out much frost, and render the growth safe. The young plants are moderately tender at this period, and it is well not to allow the shoots to be frozen. If in a slightly heated frame covering the glass is not necessary, but heat for the plants is not desirable after the first week succeeding potting unless weather be severe. Small sticks may be placed to each plant as supports.

Green fly ought not, but often does, appear in the points of shoots at this early stage, and is frequently, though not always, the result of neglect in watering or giving the plants a check in some way. The best remedy is fumigation or vaporising. Dusting the infested parts with tobacco powder one day and washing it off the next is also a capital remedy. It is seldom, however, the insects are troublesome when regular and systematic attention is given in watering and the supply of fresh air.

Another evil often asserts itself at this juncture, and this is fungoid pests. Mildew and rust are the chief, and the grower wants no more, but desires ardently to free the plants of these. Mildew lays on the leaves like a white powder. Rust appears in dark detached spots. A remedy for both forms of fungus is sulphide of potassium, half an ounce

to one gallon of water. This must be sprayed upon the foliage, first picking off the worst infested leaves which can be spared. Repeat the application until all signs of the fungus disappear and thoroughly clean and healthy leaves are present only.

As the plants advance in growth give air abundantly on every favourable occasion, avoiding cold winds. When the latter are not in evidence a little daily full exposure will be highly beneficial to the plants.—GROWER.

PRIZE GRAPES.

THE accompanying photographs portray the two first-prize stands of black and white Grapes exhibited at the last Bournemouth Chrysanthemum Exhibition, by Mr. William Mitchell of Chilworth Manor, Romsey. This gardener's skill as a grower of Grapes is now well known, notably as taking many prizes at Brighton, the Crystal Palace, Winchester, Southampton, and other shows of importance during the past eight or nine years. His exhibits of that somewhat difficult Grape, Mrs. Pince, are always good, and the three bunches of it represented in the photograph were excellent. Mr. Mitchell, like other good growers, believes in plenty of water and air. His success with that king of Grapes, Muscat of Alexandria, is equally good. The three bunches of that variety at Bournemouth Show were of a beautiful amber tint, and exquisite in shape.

The one Grape that does not succeed at Chilworth is Gros Colman, which seems the case with many growers. My experience of this variety is that it requires a long season to perfect it. It is a first-rate Grape for invalids, and in my opinion is immensely superior if allowed to hang on the Vine to acquire sweetness, which it does not seem to do if cut much before the leaves fall. If started early and given a little fire heat in autumn it is usually of a better colour than if treated as is often done with Black Alicante, that is allowed to come on late and given no fire heat in autumn.—W. J. GRACE, *Bickton, Fordingbridge*.

NOTES ON FIGS.

THE earliest trees in pots will need assistance in swelling the fruit. A top-dressing of rich material applied to the surface of the pots, space being provided for this purpose by a layer of turves placed around the rims, will afford steady supplies of nutriment. The dressings, however, should not be heavy, but a little of the rich compost supplied at weekly intervals. Liquid manure will also be useful in sustaining the health and vigour of the trees, it being better to afford a varied rather than a uniform regimen. Thus, watering with liquid manure from stable or cow house tanks, or Peruvian guano, 1 oz. to a gallon of water, will act better if a sprinkling of some approved fertiliser be given about every ten days or a fortnight. Let the water or liquid be of the same temperature as that in which the pots are placed, as a check may be fatal to the crop. Dribblers are of no use, and insufficient supplies of liquid nourishment often cause the fruit to fall.

In order to effect free development the atmosphere must be genial, syringing twice a day when the weather is bright, but avoid keeping the foliage constantly wet. In dull weather damp the paths and walls instead of syringing the trees, but an occasional syringing will be necessary to keep down red spider. If this pest appear paint the hot water pipes thinly with sulphur, using a cream of freshly slaked lime for mixing. To give the foliage consistence and enable it to evaporate freely, commence ventilating a little at 70°, increasing it with the advancing sun to 85°, which ought not to be exceeded before noon, a rise of 5° to 10° after closing being beneficial. A night temperature of 60° to 65° in mild weather, and 5° less in severe is suitable, the lower temperature being safer with a rise of 10° by day in dull cold weather. Crowding the trees should be avoided, also very close pinching, it being better to tie out or down as the growth advances, confining the stopping to nipping off the points of the unruly shoots at the fifth or sixth leaf, rubbing off those not required. This will usually give good results in the second crop.

Planted-out Fig trees that were started at the new year now require disbudding and stopping. It is bad practice to leave more growths than there is room for, and equally disastrous to allow vigorous shoots to monopolise the sap. They should be stopped at about the sixth leaf, this also favouring the swelling of the first crop Figs and their satisfactory flowering, which is essential to their perfecting. Liberal supplies of water or liquid manure, not too strong, will be required betimes, and a mulching of rich compost attracts the roots to the surface. Where the trees are in shallow and narrow borders roots may be encouraged from the collar or stem by placing pieces of fibrous turf and partially decayed manure in contact with it, and by extending the material outwards a number of feeders will be secured. If these are supplied with water or liquid manure or top-dressings of chemical manures they will greatly assist the second crop of fruit. A night temperature of 55° to 60° will be suitable. It is advisable to give a little air at 65°, increasing the ventilation with the temperature, and reducing it in like manner, closing at 70°, syringing twice a day, and otherwise maintaining a genial atmosphere.—G. A.

NOTES ON FRUIT UNDER GLASS.

THE advent of early spring, accompanied, as it is, or at any rate is expected to be, by warmer and brighter weather—free from the fog, which all cultivators around London have so much reason to

Where flowers are open on the Peach trees it is an excellent plan to pass over them lightly with a rabbit's tail, tied at the end of a rod, in order to aid fertilisation. Unless this is done a good set of fruit cannot be depended upon so early in the season. For many years we have made a practice of doing this, and largely attribute our heavy crops of fruit to its effectiveness. The tiny Peach shoots also must be gradually thinned, a few of them (about one-third) every other day.

Winter Cucumbers are rather difficult to manage successfully, especially if a long spell of dull weather is experienced. Although plants which become well established in their permanent quarters by October are very satisfactory for winter fruiting up to January, we find that a house planted early in November (although the occupants of it are never so strong and healthy as earlier established plants) produces some few fruits throughout the winter months. At the present time, as the weather improves week by week, they make fresh growth, and we are now cutting fruits from them, and shall continue to do so until March, when plants from seeds sown in December will come into bearing. The earliest Melons, sown also in December, for yielding fruit by the month of May, are in 48-pots, ready to be planted out on a hotbed so soon as this is prepared for them, while the seedlings from the second sowing are well rooted in small pots, and will soon require moving into larger ones.

In many gardens the earliest Strawberry fruits are now swelling. To insure as good a development as possible at this season they ought to be placed on a shelf near the glass in a warm Pine pit, where the night temperature does not fall below 70° Fahr. Syringe them frequently and water with liquid manure. Unless a house is available solely for Strawberry culture these plants entail a great deal of labour

in a short time. Until the flowers are produced and commence to open a Cucumber house is an excellent place for them, although we always endeavour to have a heated pit filled with leaves wherein to plunge the pots for a few weeks before. As soon as the flowers expand it becomes necessary to transfer them to another house where more air can be given, and again after the fruits are set a warm moist atmosphere is requisite.

It is most disheartening to attempt the culture of Beans during

FIG. 46.—GRAPE MUSCAT OF ALEXANDRIA.

dread—brings in its train a large increase in garden work, no less to that of the outside departments than of the section under glass. At the present moment, however, it is more particularly to the work connected with the latter that I would refer, and then only to those houses devoted to the cultivation of forced fruits and vegetables. By now all vineries and Peach houses should have been thoroughly cleaned and set in order for another season; the early ones, of course, will have been started for some time.

Our method for cleansing the Vines and vinery is first to burn a small amount of sulphur in the house, after closing the latter. This is accomplished by placing a 6-inch pot in the centre of the vinery, half filling it with red hot coke; upon this a good handful of sulphur is placed, and the fumes arising from it are allowed to fill the house. This may seem a somewhat dangerous practice to recommend, but we have not found any evil results to accrue from following it, when carefully and judiciously performed; and it is certainly a most excellent method of cleansing a vinery of insect pests. The following day the Vines are brushed over (taking care not to touch the buds) with a solution made by mixing 2 lbs. of softsoap with a little warm water, and when the two have become thoroughly incorporated adding two wineglassfuls of paraffin. Three gallons of warm water are then added, and the insecticide is ready for use. If other important work presses, instead of brushing over the Vines we simply syringe them with the above mixture, at the same time endeavouring to apply this to all holes and corners where mealy bug is likely to be hidden. Finally the vinery is well washed down with a large hose, and if the walls need to be limewashed this is done. We always remove a few inches of the surface soil from the border after the house is finished, and top-dress with fresh loam, with which artificial manure has been mixed.

In the Peach houses we do not use sulphur, but simply apply the hose to the woodwork and other surfaces, and syringe the trees with softsoap and warm water only. In the earliest Peach houses and vineries there will be much to occupy one's time. In the former disbudding is needed, and in the latter stopping and tying the shoots require attention.

FIG. 47.—GRAPE MRS. PINCE.

winter within reach of London fogs. We have this season lost several hundreds of pots of these plants by reason of heavy fogs causing the flowers to fall. When Beans should be sown depends, of course, on the time they are required, and will therefore be governed by local

circumstances. In spring Beans may be gathered in six or seven weeks from sowing, though in winter eight or nine weeks must elapse between these two operations. We find 8-inch pots to be the most suitable, though before Christmas 6-inch are to be preferred, for growth is not then so vigorous, nor is so much water required as later in the season.

The flowers are just opening on our Tomato plants for spring fruiting. These are raised from seeds sown in September, gradually shifted into 10-inch pots, and in December are plunged in a bed of leaves made up in a warm pit. A most useful crop of fruit is gathered from them during March and several succeeding weeks. Seedlings from successional sowings, now 3 or 4 inches high in small 60-pots, will probably require transferring to larger pots, and ought then to be removed from the intermediate temperature, in which when young they grow best in winter, into cooler quarters, always keeping them near to the glass. In the case of Tomatoes for early spring fruiting, when they are in flower artificial fertilisation is essential to the production of a satisfactory crop of fruit.—H. H. T.

THE SWEET PEA BICENTENARY.

UNQUESTIONABLY the popular flower for 1900 will be the Sweet Pea, and this is not to be wondered at when the ease with which these delightfully fragrant flowers can be cultivated is considered, or when memory recalls the exquisitely beautiful colour, shades, and combinations seen in 1899. The Sweet Pea also shows some amount of variation in form, which is the more remarkable in these days when hybrid flowers are abundant, for the Sweet Pea has been evolved by the patience of the florists from one species—viz., *Lathyrus odoratus*, introduced 200 years ago. If other proof were needed that the Sweet Pea is to be the flower of the year, it is to be found in the enthusiasm with which the project for celebrating the bicentenary of its introduction at the Crystal Palace, Sydenham, on July 20th and 21st next, is being supported by amateurs, professional gardeners, and seedsmen throughout the United Kingdom.

On February 23rd the second meeting of the Celebration Committee was held at the Horticultural Club, Hotel Windsor, Victoria Street, S.W., when Mr. George Gordon, V.M.H., Chairman of Committee, presided over a good attendance that included members from towns as far distant as Birmingham and Cardiff. Accepting special prizes and finally revising the schedule was the chief work of the evening; and now this part of the business has been completed, we are at liberty to state that thirty-four classes are provided, none with less than four, and some with five, prizes. These classes range from one for one hundred bunches of Sweet Peas, with a first prize of £10, down to those for a single bunch of one variety, with a first prize of 8s. It is difficult to see how a more comprehensive schedule could have been drawn up, for provision is made alike for the small and the large grower, the artisan and the millionaire, while the value of the Sweet Pea for a home decoration will be demonstrated in classes for table decoration, florists' designs, epergnes, baskets, and bouquets. The total prize money offered amounts to £140, and in addition to this a fine champion silver cup is offered for the best amateur exhibit at the celebration show. In no less than nineteen classes the prizes are offered by well-known horticultural firms whose names will appear in the schedule that will be ready for publication immediately.

In the preliminary notice of the Committee, published less than two months ago, the cost of carrying the celebration to a successful issue was estimated at £300; and towards this sum nearly £230 has already been promised. So much success having already attended their efforts, the Committee feel justified in hoping that now the schedule of prizes can be obtained upon application to Mr. R. Dean, V.M.H. (Honorary Secretary), Ranelagh Road, Ealing, W., the further amount necessary to the proper carrying out of all details connected with the exhibition and conference will speedily be forthcoming. A decidedly international flavour will be imparted to the Conference proceedings, as, in addition to British specialists, Mr. W. Atlee Burpee, of Philadelphia, U.S.A.; Mons. Vilmorin, of Paris; Mr. Benary, of Erfurt, and Mr. Krelage, of Haarlem, are expected to attend, and have all meanwhile shown practical sympathy with the movement by providing special classes. The class for American raised Sweet Peas should prove not the least interesting at the forthcoming exhibition.

As the forty members composing the General Committee represent such a large area of the United Kingdom, it was thought desirable, both to facilitate matters and save the incurrence of heavy personal expenses on the part of those residing many hundreds of miles away, to form a small Executive Committee, to carry out the remaining details. The General Committee will, of course, be called as necessity demands. Those gentlemen elected to serve on the Executive Committee are: Mr. George Gordon, V.M.H., Chairman; Mr. E. Beckett, Elstree; Mr. C. H. Curtis, Brentford; Mr. J. Fraser, F.L.S., Kew; Mr. H. J. Jones, Lewisham; Mr. J. F. McLeod, Roehampton; Mr. H. A. Needs, Woking; Mr. R. Sydenham, Birmingham; Mr. H. J. Wright, Wandsworth; and Mr. R. Dean, V.M.H., Ealing.

PATSHULL.

THIS is the princely Staffordshire seat of the Earl of Dartmouth. Unfortunately, I am unable now to give any account of the house or its historical associations, while as the time of my visit precluded note-taking the account will, I am afraid, be somewhat imperfect, and fail to do the gardens, which are under the management of Mr. Halliday, proper justice. The grounds are filled with fine Coniferae and evergreens, and there are 8 acres of kitchen garden. The whole of the south wall is surmounted by a glass coping, beneath which are planted Plums and Apricots.

The houses, twenty-two in number, are principally situated in a large square, with the exception of the large conservatory, which is a short distance away. The first houses I entered were two spacious structures devoted to Melons, but which, at the time of my visit (early in January) were occupied with *Ixoras*, *Gardenias*, and *Tabernaemontanas*. Continuing this range was the early vinery, 60 feet long, planted alternately with Black Hamburgh and Foster's Seedling, with Figs on the back wall. Following this, and of the same dimensions, was a division occupied by Muscat of Alexandria Grapes, Figs again having the back wall. All the Vines are comparatively young, and Mr. Halliday evidently recognises the importance of young Vines with short spurs in contradistinction to old ones with long naked spurs. In the late vinery were hanging seventy perfectly finished bunches of Black Alicante, which for size of berry could hardly be surpassed. There are six vineries in all. I had almost forgotten the fine plants of Strawberries in the early vinery, mostly *Vicomtesse Hericart de Thury* and *Leader*, in 5-inch pots.

There are also two Peach houses, each 70 feet, and sufficiently wide to accommodate trees both on the front trellis and back wall, and their general appearance betokens the best of health. The late Peach house is 120 feet long, and in common with the others is a noble structure. Space is found also on the back walls of these for a Fig tree or two, so that a continuous supply of this delicious fruit is maintained. The Peach trees are models in training that none would err in copying.

The Palm house contained two large plants of *Monstera deliciosa* showing fruit. The roots of these have access to a water tank, which they evidently enjoy. A span-roofed stove was filled with small decorative plants of *Crotons*, *Pandanus* and winter flowering *Begonias*—viz., *Gloire de Sceaux* *President Carnot*, and *metallica*. *Malmaison* *Carnations* are a great feature, and their wonderful health, luxuriance, and vigour are a credit to Mr. Halliday and his foreman, Mr. Roberts. The same system is practised as was so successfully carried out at Rangemore and Byrkley Lodge, and I believe has been fully described in the pages of the *Journal of Horticulture* by Mr. Wm. Baidney. The house devoted to them is span-roofed, having ventilators at the top and sides. It runs north and south, and contained 1000 plants. Rust, spot disease, and insect pests are evidently unknown, the plants having that glaucous hue so beloved of enthusiasts, and their broad recurving leaves hang over the sides of the pots. The central step-like stage held 250 two-year-old plants, in 8-inch pots, with from eight to twelve vigorous shoots. The side stages had 800 last year's layers in 5-inch pots. A constant circulation of air is maintained, and should the weather be wet or foggy a little heat is afforded to maintain a buoyant atmosphere. Watering is most carefully done; the plants at no period are allowed to become very dry, while on the other hand excess is avoided.

Another structure of similar size was completely filled with hundreds of healthy young plants of tree *Carnations*, such as *Madame Carle*, *Winter Cheer*, *Mrs. Leopold de Rothschild*, *Mdlle. Thérèse Franco*, and on the side stages, mostly in 5-inch pots, were scores of young plants of Mr. Martin Smith's hybrid border *Carnations*, many of which were in flower.

Orchids are apparently not a desideratum, but one house contained a small collection of *Cattleyas*, *Laelias*, *Cypripediums*, and *Dendrobiums*. Another house was stocked with about fifty large, healthy plants of *Eucharis amazonica*, which from their grand appearance must produce immense numbers of flowers. In the same house were some splendid *Gardenias*. In various other houses I observed collections of *Freesias* and *Lilium Harrisii*. In one house there were two dozen plants of *Reinwardtia tetragyna* full of their golden flowers. *Siphocampylus Humboldtianus* is also grown, while two dozen plants of *Myosotis Imperatrice Elizabeth* in 5-inch pots were charming in their inimitable blue. *Cape Pelargoniums*, *Diosma ericoides*, and other scented-leaved plants have a goodly amount of space, and several pits were filled with Violets.

The conservatory, 100 feet by 45 feet, and 20 feet high, has a double longitudinal ridged roof. The sides, roof, and pillars are clothed with various creepers, including *Cassia corymbosa*, *Tecoma capensis*, *Solanum jasminoides*, *Plumbago capensis*, *Datura sanguinea*, and climbing Tea, *Noisette*, and *Bourbon Roses*. *Rose Souvenir d'un Ami* was noticed in profuse bloom, whilst a plant of *Luculia gratissima* had at least 150 trusses of its charming flowers. On the parqueted floor, arranged singly, were specimen *Camellias*, *Myrtles*, *Tree Ferns*, and large *Palms* with small groups of flowering plants of *Azalea Deutsche Perle* and *Freesias* at the base. On the narrow side stage I observed well-grown *Calanthe Veitchii* and a number of good *Begonia Gloire de Lorraine*.—F. STREET.

Recent Weather in London.—The weather continues very mild and unseasonable, and many persons would hail with pleasure a spell of gentle frost. Such would be beneficial to almost everyone and everything. Sunday was dull but dry throughout the day, while Monday morning was characterised by a veritable downpour of rain. It cleared later in the day, but the evening brought another deluge. On Tuesday and Wednesday it was wet and very muggy.

Northern Weather.—Snow fell on the 20th, and again on the 22nd, causing fresh blocking of roads that had just been opened, in several parts of the country. On the morning of the 21st there were 8° of frost, but latterly the weather has been dull and foggy. The afternoon of Sunday, however, was bright and fine, while Monday was dull and cold with a bitter wind from the east.—B. D., *S. Perthshire*.

The Gardeners' Charity Guild.—The fourth annual smoking concert of this Association will be held on March 14th, at 7.30 P.M., in the Great Hall, Cannon Street Hotel, E.C. N. N. Sherwood, Esq., will occupy the chair, and the proceeds will go to the Gardeners' Royal Benevolent Institution. Tickets are obtainable from members of the Guild, price 1s. each, or from the Hon. Secretary, Mr. T. Swales, 5 and 6, Clement's Inn, Strand W.C.

Chester Paxton Society.—At the usual fortnightly meeting, held at the Grosvenor Museum on Saturday, Mr. R. Newstead, F.E.S., consulting entomologist to this Society, lectured on "Recent Important Investigations on the Currant Bud Mite" and notes on the "Pear Tree Slug," Mr. N. F. Barnes in the chair. In his opening remarks the lecturer gave an account of the life history of the Currant Phytoptus, dealing with all the salient points of its economy. As a result of present knowledge of the habits of the pest it has been found impossible to apply any effective insecticide at the time of migration owing to the long period over which it is continued. He then went on to describe numerous experiments which had been conducted at Woburn with approximate results obtained. Not the least of these were a series of experiments which Mr. Newstead had recently conducted with hot water. Complete and lengthy immersion is, however, necessary for the killing of the mites, but which it is feared will also, as many other things have proved, prove fatal to the plants. The second part of Mr. Newstead's paper described many new facts dealing with the Pear tree slug, including results of experiments with insecticides, in which it was pointed out the uselessness of a top-dressing of lime. An interesting discussion followed, in which Mr. Robert Wakefield, President of the Society, Mr. G. P. Miln, Honorary Secretary, and others took part, and at the close a hearty vote of thanks was accorded to Mr. Newstead for his able and interesting lecture.

Reading Gardeners' Mutual Improvement Association.—"Horticultural Buildings" was the subject of an interesting and practical paper read before the members of the above Association on Monday last by Mr. G. H. Parsons, horticultural builder, Reading, who in a few preliminary remarks said that horticultural buildings, as compared with religious and domestic buildings, are quite modern. The last 200 years will nearly cover all records. Their necessity arose from the bringing home by travellers and others of plants and seeds that would not stand the rigours of our climate. The modern and popular taste for Tomatoes and Cucumbers has caused the erection of thousands of houses. Prolongation of season of different fruits, flowers, and vegetables, is also another prolific cause of construction. After explaining the action of the rays of light passing through glass at various angles, Mr. Parsons passed on to the consideration of glass and roof pitches, sites, forms of houses, heating, staging, pathways, brickwork, timber, ironwork, glass and glazing, and painting. Many questions were asked, and an exceedingly interesting discussion followed, in which the following took part—Messrs. Woolford, Hinton, Fry, Neve, Pigg, Purkis, Cretchley, Rigg, Bryant, Ager, and Dore. At the close a hearty vote of thanks was accorded to Mr. Parsons for his paper, and to Mr. Pigg, The Gardens, Samoa Villa, Kendrick Road, for exhibiting a beautifully coloured *Amaryllis*.

New Recreation Ground.—The Archbishop of Canterbury has consented to hand over the Lambeth Palace Grounds to the London County Council for use as a public recreation place.

Croydon Gardeners' Society.—Croydon has awoke to the fact that a mutual improvement association is necessary for gardeners and others interested in horticulture. A society has been established with the title of "Croydon and District Horticultural Mutual Improvement Society," and at a well attended inaugural meeting, on February 20th, Mr. George Gordon, V.M.H., discoursed pleasantly on combinations of gardeners. The Secretary is Mr. John Gregory, 60, Canterbury Road, Croydon.

Bristol Gardeners' Association.—The fortnightly meeting was held at St. John's Parish Room on Thursday, 22nd ult. Mr. Chas. Lock presided over a good attendance. The paper was supplied by Mr. A. Moore-Sara of Elmside, Stoke Bishop, on "The Pollen Grain and its Functions." With the help of black board diagrams he made the subject very interesting, tracing what is known of the conception of the sexuality of flowers from the time of Herodotus down to the 17th century, when in 1676 Dr. Grew in a book on plant anatomy laid down in definite terms the law of vegetative impregnation, accepted by botanists to-day, and in a greater or lesser degree understood by all present day gardeners. Dealing in detail with the subject, he described the formation of the pollen, some of the many methods of distribution, and the processes through which it had to pass until fertilisation was complete. A short discussion followed, chiefly on the advisability of forming a botany class in connection with the association. Prizes for three pots of Narcissi were secured by Messrs. Price and Ross. Certificates of merit went to Mr. White and Mr. Clarke each for an Orchid in bloom.

Irish Gardeners' Association.—The members of the above Association held their monthly meeting on Thursday last, the 22nd ult. Mr. Cotter, President, occupied the chair. Mr. A. Campbell, The Gardens, St. Anne's, Clontarf, gave a lecture on "The Treatment of Plants From Different Climates." At the outset he regretted the absence of young men, as it was to them he intended to devote his paper. He desired to impress upon young gardeners the absolute necessity of learning something more about plants than the usual routine. He should try and learn the natural conditions of the plants from the countries where they are indigenous—namely, the soil, climate, the changes of the seasons, and the temperature they thrive in; in fact his business was to imitate nature, and he could only acquire this knowledge from a thorough study of books of travel. He then dealt with numbers of plants as illustrative of his remarks. Several questions were put to the lecturer, which he answered, after which a discussion arose as to the wisest course in planting Vines, whether when growing or dormant. A vote of thanks, proposed by Mr. Shaw, and seconded and supported by several members, was unanimously passed to the lecturer, after which the meeting was brought to a conclusion.

Birmingham Gardeners' Association.—Much interest was centred in the last fortnightly meeting (February 19th) by the fact that there was to be a series of about 100 photographic limelight pictures of various objects of interest pertaining to garden scenes and of natural history contained in the pleasure grounds of Harborne Hall, Harborne, the residence of Walter Chamberlain, Esq., brother of the Colonial Secretary. The photographs were taken by the head gardener, Mr. C. R. Bick. Mr. W. B. Latham, the Chairman, in introducing the lecturer, remarked that he himself had had ample opportunity of witnessing the progress of the numerous improvements effected by Mr. Bick. The subject was entitled "A Walk Round Harborne Hall Pleasure Grounds," and a verbal description was given of each view, accompanied by a few characteristic humorous remarks and anecdotes. Especially interesting were such views as the artificial "Serpentine Pond" in near proximity to the handsome and commodious mansion. The formation and furnishing of the pond was an object of Mr. Bick's special regard, and altogether it represents an ideal water garden. The "Lower Pond" is the abode of several species of waterfowl, including specimens of penguins. Effective pictures were also portrayed of a colony of ostriches and cranes in considerable variety, one or two species of the latter genus being very rare. Photos of zebra bulls and cows with their peculiar "humps," as seen in their respective quarters, the paddock and the farmyard, afforded additional interest to the display. A hearty vote of thanks was accorded Mr. Bick for his unique and interesting exposition.—W. G.

Gardeners' Royal Benevolent Institution.—We learn that his Grace the Duke of Portland has kindly consented to preside at the annual dinner of the Gardeners' Royal Benevolent Institution, to be held in the Whitehall Rooms of the Hotel Metropole on Friday, May 18th.

United Horticultural Benefit and Provident Society.—The annual general meeting of this Society will take place at the Caledonian Hotel, Adelphi Terrace, Strand, on Monday, March 12th, at 8 P.M. Mr. S. T. Wright, of the Royal Horticultural Society's Gardens, Chiswick, has kindly consented to preside.

Railway Embankments.—It has been noticed that many plants, not natives of the locality, are to be found growing in the neighbourhood of great railroads. Sometimes the seeds of these plants have been brought thousands of miles from their natural habitat. Often they flourish amid their new surroundings, and gradually spread over the surrounding country. Thus the railroads carry unsuspected emigrants, which travel to and from every point of the compass.

Gardening Appointments.—Mr. Joseph Tindall, for nearly nine years head gardener at Coed-y-Maen, Welshpool, has been appointed head gardener to Albert Wood, Esq., Bodlondob, Conway. Mr. John Logan, late gardener to G. de Belle Ball, Esq., Lisson Hall, Swords, co. Dublin, has been appointed head gardener to W. Woodburn, Esq., The Hermitage, Rathfarnham. Mr. A. Browne, late head gardener to — Pim, Esq., of Stradbroke Hall, has been appointed to a similar position in the gardens of Mrs. Henshaw, St. Philips, Milltown, in succession to Mr. McKay. Mr. R. Reader, late foreman Marks Hall, Essex, to be head gardener to R. A. Ellis, Esq., Greenwoods, Stock, Essex. Mr. A. Ward, for the past seventeen years head gardener, and latterly sub-agent at Stoke Edith Park, Hereford, has been appointed head gardener to F. A. Bevan, Esq., Trent Park, New Barnet, in succession to Mr. W. H. Lees, who is starting business for himself as a fruiterer and florist.

Shirley Gardeners' Association.—At a recent monthly meeting of above Society, held at the Parish Room, Shirley, Mr. B. Ladhams, F.R.H.S., presided. Mr. E. T. Mellor, B.Sc., London, Lecturer in Biology in the Hartley College, Southampton, gave an illustrated lecture on the "Composition of Chemical Manures and their Application to Various Soils." This was most interesting, his first object being to illustrate by means of a series of chemical experiments, the making of a phosphate from a small portion of phosphorus, thus thoroughly explaining to his audience the nature of a "phosphate," of which there are many kinds. The application of chemical manures to the ground was shown by another series of chemical experiments to be a matter requiring considerable care. Mr. Mellor stated that some of the Colonial Government departments made an analysis free of cost of all soils sent to them, thus enabling growers to select and use the manures most useful and economical in each case. A vote of thanks was accorded to Mr. Mellor at the close of his remarks.

Royal Meteorological Society.—The monthly meeting of this Society was held on Wednesday evening the 21st ult. at the Institution of Civil Engineers, George Street, Westminster. Mr. E. Mawley, F.R.H.S., read his report on the phenological observations for last year, in which he showed that the weather for the year ending November, 1899, was chiefly remarkable for its high temperatures, scanty rainfall, and splendid record of sunshine. The winter and summer were singularly warm seasons, while the autumn was also warm, but during the three spring months rather low temperatures prevailed. In the early part of the flowering season wild plants came into blossom in advance of their mean dates, but after March they were mostly late in coming into bloom. Taking the country as a whole, the best farm crop of the year was Wheat; the yield of Barley proved also good, while Oats were slightly under average. The crops mostly affected by the dry weather were those of hay and Turnips, the latter being in most districts exceptionally poor. The only part of the British Isles where the summer drought was not severely felt was in Ireland, throughout a great part of which there was abundant keep in the pastures during the whole summer. This year was a very bad one for fruit. The yield of Apples, Pears, Plums, and Strawberries varied greatly in different localities, but was in most of them much under average. Dr. R. H. Scott, F.R.S., read a paper giving the results of the percolation experiments which have been carried on at Rothamsted by Sir J. B. Lawes and Sir J. H. Gilbert from September 1870 to August 1899.

Honour for a Gardener.—We learn that Mr. A. MacKellar, the chief of the Sandringham Gardens, has had conferred on him by the Emperor of Germany, the Royal Order of the Crown of the Fourth Class.

Mr. A. F. Barron.—The many friends of this well known horticulturist will have sympathised with him in his very prolonged illness. This has prevented his leaving the house for a considerable period, and we learn with regret that his enforced confinement has to be still further extended, as though much improved in health he must not risk the unfavourable weather conditions that now prevail.

The Tulip Tree.—The only objection I know to the planting of this tree in exposed situations is the extreme brittleness of the wood. Every year when we get the usual equinoctial gale, during the first or second week in September, the Tulip Tree loses a few branches, in number and size according to the severity of the gale of course. Our specimen is not less than 60 feet high; it is protected on the south-west by other trees, but in spite of this it suffers. The deep green of its leaves in the summer, and the golden hue of autumn, are much more attractive than its blossoms, which in my opinion are quite insignificant.—E. M.

Lawns and Other Grassy Grounds.—The full title of a quarto book of a couple of dozen pages which we have received from Messrs. J. Carter & Co., High Holborn, is "Lawns, Lawn Tennis, Cricket, Golf, and Other Grassy Grounds," and this may be considered sufficiently comprehensive to explain its contents. The information given in the various sections treated of is thoroughly sound and reliable, and will prove of much value to those persons who have such spaces to lay out and keep in proper condition. The book is printed on excellent paper, and is profusely illustrated with photographic views of many of the grounds in which Messrs. Carter's seeds have been utilised.

Weather in Guernsey.—After a dry warm autumn, the month of December set in unusually cold, with some sharp frosts in the middle of the month. Since Christmas Day we have had one long spell of wet, with only an average of about two dry days in a week, and a much varying temperature; we are in consequence very backward. The want of sun for our early crops under glass has had a very retarding effect, and in some cases they have gone off altogether especially French Beans; and unless a change comes soon the Peas will assuredly suffer from mildew. The high price of anthracite coal, too, is pressing hard upon growers, especially those who failed to lay in stocks in the autumn; the cost, including wharfage dues and carting, being now close on 30s. per ton. At this time last year we had commenced shipping Daffodils pretty freely, but scarcely any have gone this year yet; however, given a few warm dry days, and we shall soon see a very marked change. Tomato planting is being vigorously pushed on now. The early birds who planted in January will, I fear, not come off very well this time, the dull sunless weather having prevented a decent show of bloom being formed.—X.

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet.

A dull, damp week, with brief intervals of bright sunshine. Southerly winds prevailed; the latter part of the week being very mild.

PINCHING FRUIT TREES.

AFTER reading carefully "A Lincolnshire Gardener's" article on page 154, in which he advocates pinching in arguments extending over nearly two columns, I was somewhat staggered at coming to this sentence—"With unlimited space, and for utilitarian purposes, I should adopt a different method." Does this mean that if "A Lincolnshire Gardener" were a market grower, cultivating 20 acres or more of fruit trees, he would not pinch? And what is his "different method?" If it pays to pinch a quarter of an acre, it would pay to pinch twenty, or even a thousand acres, the only question being whether sufficient skilled labour was available or not. But I have yet to find the extensive market grower who pinches, or even summer prunes, and I have visited many very successful growers. On the Woburn Experimental Fruit Farm a trial of summer *versus* autumn pruning had not brought out any difference up to the autumn of 1898.—LEARNER.

SEEDSMEN'S GUARANTEES.

WHY should Mr. C. E. Pearson (page 137) assume that a seedsman who guarantees that his seeds were true to description and as ordered would have an unhappy existence? Is not such a statement calculated to create distrust of the seed trade, both in relation to its honesty and its capacity to supply to purchasers what is ordered from the seedsmen's lists? Is it not a fact that 99 per cent. of all seeds supplied to customers by good firms now, irrespective of guarantee, are found to be absolutely as anticipated when growth takes place? That being so, why make such a wry face over the guarantee clause, which is at the best anything but an honourable one if it covers such an act as was that which originated this discussion? All these quibbles about variations are beside the mark. They exist very much in the imagination, or are non-existent. Why should any seedsman who tests his seeds be afraid to guarantee their exactness to description? To me such excuses are incomprehensible.—A. D.

JUDGES AND JUDGING.

DURING the past quarter of a century the pages of the *Journal of Horticulture* have seen many discussions, all more or less valuable to the gardening community. Some of these have been participated in by large numbers of readers; while others have been confined to a limited, and perhaps I might venture to say select circle. Taken as a whole these controversies have covered a very wide area, and have embraced almost all side lights of the craft. Nevertheless, I venture to bring forth still another matter which, so far as my memory serves me, has never been thrashed out in the *Journal*, and in doing so, while I recognise that I shall incur the wrath of many of its readers, I believe the subject will be one of as broad an interest as any of its predecessors, and will be provocative of numerous letters from men of vast experience, whose just claims for an audience will probably be much greater than my own. I bring the matter forward for discussion in the honest belief that it is for the benefit of both gardeners and gardening.

Without further preamble let the question be propounded—namely, "Should the same Judges be employed year after year in the same classes at the same show?" As one who has officiated in this capacity at many exhibitions I am constrained to answer in the negative. Everyone of us can point to exhibition committees throughout the length and breadth of the land who invariably select the same men, either because they have been before, and "we know him," or because they bear names prominent in contemporary horticulture. The latter clause may, broadly speaking, be a safe one to work under, but unfortunately sufficient discrimination is not always exercised in allocating to the adjudicators the section for which they are peculiarly adapted. For example, a man who as a judge of Grapes may be unsurpassable in dealing with Chrysanthemums or Roses be very much at sea. Of course it may be argued that if a man can adjudicate on one product he will be equally capable at another, but with this doctrine I most emphatically disagree. The present is largely an age of specialism, and the man who loses his *metier*, so to speak, is liable to find many pitfalls.

But it may be said that the remarks in the above paragraph apply only to the greater shows, such as Edinburgh, Shrewsbury, York, Hanley, and others, and that smaller societies are compelled to engage men of all-round capacity for their annual events. The truth of this must be readily admitted, as it would be obviously impossible for small associations to employ specialists for their limited shows. It is, however, mainly to societies of this nature that these remarks must apply, for no one can gainsay the fact that they are inveterate sinners in the direction indicated. As regularly as summer succeeds spring they employ precisely the same men, and in doing so I hold that they do not do the best they can for those who support them—i.e., the exhibitors. Do not let it be inferred that in saying this I would impugn the integrity of the Judges; nothing is farther from my thoughts. These men may and generally do carry out the duties sought

from them in the most painstaking and conscientious manner from their own point of view, but whether in doing so they always do justice to exhibitors is quite another matter.

It must be unnecessary to state that I have my reasons for the views set forth, and as the controversy proceeds I shall be ready to place them before my antagonists and supporters (for I hope to get the latter a well as the former). For the moment, however, I shall say no more, but content myself with calling upon readers of the *Journal of Horticulture* to reply to the question here repeated, "Should the same Judge be employed year after year in the same classes at the same show?" and will subscribe myself as—AN INQUISITOR.

A CAPE FRUIT GROWERS' ASSOCIATION.

THERE has been a considerable amount of discussion in our *Journal* of late about the production of fruit at home; but does it not strike many readers, and more especially young men like myself, that there will be at the conclusion of the war, terrible though it is, a grand opportunity for opening up a trade in fruit production in South Africa for local and home markets? There are too many gardeners here at home. Can we not organise a band of men, young, intelligent, and strong, to go and take up our abode at the Cape and show men at home what Englishmen can do?

I am willing to go, and have enough to keep me for six months after my passage is paid. Who else has anything to say on this subject? Now is the time for action.—GOLD PENMAN.

AN ANCIENT PEAR.

I AM enclosing photographs of a Pear tree that was planted at least sixty years ago against my old house. In 1854 alterations in the building were made, and a glazed roofed passage was arranged from the kitchen to a new scullery and back premises. My father did not wish to destroy the tree altogether, so it was "beheaded," the skylight built round it, and the top left just outside the top of the lean-to glazed roof, to grow as it liked.

The passage, of course, was paved, and outside is a paved yard, enclosed by a wall 20 feet from the house, against which the tree grows. No sunlight, therefore, can get to the roots, and no water is given; yet we always gather a good crop, whatever the season. Three years ago I thinned a good many of the old branches, leaving younger wood, and that is the only pruning it has had. In 1898 we had a very light crop in consequence, but this year (1899) we have gathered 700 Pears, and one branch broke down from the weight of fruits. I am told the variety is Hacon's Incomparable.—M. L. GAYTON.

[The photographs were most interesting, but unfortunately they were not suitable for reproduction.]

DECADENCE OF WALL TREES.

My generous opponent, by the tone of his rejoinder on page 117, engenders the feeling that one would rather join hands with him than bring any more maxims to bear upon his position. Moreover, any amount of cross firing will probably leave the matter pretty much the same. One word more, however, in order to clear up a statement of mine which is somewhat hazy. With reference to his fourth paragraph anent "the wall trees of the Queen," the maxim I employed which drew the fire of his piquant pen was really intended to cover the whole ground, but, somehow, between the penning and the printing part was lost, causing the remainder to fall short and to fall flat. If "A. N. O." is a student of Dickens he will recollect in "Martin Chuzzlewit" a certain newspaper being addressed "Queen Victoria, Tower of London," and the effect it was contemplated to produce. His original article impressed me as being quite as likely to reach its intended destination. There are gardeners *and* gardeners, but one feels it to be somewhat derogatory to the vocation to class as such men who from sheer ignorance or wilful neglect bring about such a muddle as my courteous counter-critic depicted.

The examples given by "A. N. O." on the same page are very pertinent, but come clearly under those heads—viz., ignorance or neglect—and for either it is hard to find an excuse. In one case the man has accepted the responsibility of a position for which he has neither qualified himself nor been qualified to fill. He may be a splendid plantsman, a grand vegetable grower, all of which is magnificent; but it is not gardening as I understand it in its application to the upkeep and the output of a gentleman's garden. Should such deplorable results arise from neglect then comment is needless. In either case the man responsible for it is not a gardener in the comprehensive sense of the term; that he may be called so is another matter and another tale. There is, however, a grand moral in "A. N. O.'s" communication which will, probably, be utilised for the benefit of the rising generation by—A. N. OLDHEAD.

THE WEATHER OF 1899.

THERE is a weather proverb which says, "A dry year never beggars the master." Recent years have proved that this saying is on the whole a very true one, but for once it has undeniably proved a failure; and it is certain that all interested in farming and all other branches of agriculture will long remember the disastrous effects upon vegetation of the great heat and drought of the summer of the last year but one of the nineteenth century. The summer, indeed, was by far the most remarkable within living memory, and its great heat is undoubtedly the most important meteorological phenomenon of the year.

In many respects the chief features of the year bear a striking resemblance to those of its predecessors. The same warmth in each case characterised the opening months, followed by a cold spring, hot dry summer, and mild autumn. In some other respects, however, the weather was vastly different; December in the one case being warm almost beyond precedent, and in the other much colder than the average; while in 1898 the warmth at the commencement of the year was accompanied by wonderfully fine dry conditions, but in the year under review January and the first half of February were characterised by very stormy and wet weather.

These unsettled conditions were succeeded by very fine dry weather during the latter half of February, and also throughout the greater part of March, with the exception of a very severe period of cold from the 16th to the 25th. April was wet and somewhat cold. May, for the second year in succession, was very cold; fine weather, however, prevailed at the commencement and end of the month, the middle portion being wet. With June came an entire change from the inclement conditions of the spring to sunshine and warmth, this continuing with the exception of a few cold days at the commencement of July until half of September was gone, when autumnal conditions set in. After a period of wet and somewhat stormy weather during the next fortnight conditions again became settled, and the greater part of October was wonderfully fine, although at times foggy in some districts. November commenced with ten days or so of considerable rainfall and a good deal of wind, but then again fine weather returned, lasting until the close of the month, with much fog, however, and generally dull skies. The last month of the year was as a whole cold and wintry.

Although it is impossible to give an exhaustive account of the rainfall of the year, its general distribution over our islands will be seen from the following table, which gives the details of fall at eight selected stations.

The rainfall upon the whole, therefore, was generally deficient, although not nearly to the extent that it was in 1898. It will be seen that March and the three summer months show the greatest deficiency, the falls at some stations during the first and last of these months being remarkably small. In December unusually heavy rainfalls occurred in the west and south of Ireland, totalling, it will be noticed, to over 11 inches at Valencia.

Mean atmospheric pressure over our islands was generally in excess of the average after February, with the exception of April, September, and December. The greatest pressure reported at 8 A.M. was 30.77 inches at York, on January 26th: and the least 28.30 inches and less, over the south-west of our islands, on December 29th—a range of $2\frac{1}{2}$ inches.

The mean temperature of the twelve months is considerably in excess of the averages. In the second table given the means for each month and also for the year at eight stations situated over our islands will be seen.

The means are those of the daily maximum and minimum readings, and are not corrected for diurnal range. The means for only two months, May and December, show a general deficiency of temperature over our islands. On the other hand the figures for February, the three summer months, and November are almost without exception in excess. January also was warmer than the average, except in the North, and October excepting central England, where the anti-cyclonic conditions prevailing throughout the greater part of the month caused somewhat low temperatures during the night time. Taking the year as a whole, it was slightly cooler than its predecessor, chiefly owing to the great difference of the means for each December, this amounting to no less than 10° at some stations. The greatest temperature reported over our islands during the year was 90° at London on August 25th, and the least 8° at Loughborough on December 14th, a range of 82° .

With the exception of the short period of excessive cold in March, the year was entirely free from severe snowstorms. During this period some heavy storms occurred in the north and north-east. Thunderstorms were fairly frequent throughout the summer months. Many storms also occurred during the winter, spring, and autumn, March being the only month during which none were reported. In the south-west of England some exceedingly heavy storms occurred early in February.

Gales were very frequent during January, and the earlier parts of February and November; but taking the year as a whole they were not very prevalent. The most serious occurred on January 12th, generally over our islands; and on April 7th on our western coast. —H. H. HARDING, F.R.Met.Soc., Bristol.

BEGONIA GLOIRE DE SCEAUX.

THIS Begonia is one of the handsomest both in leaf and flower of the winter-flowering section of these useful and attractive plants. It merits extensive culture, alike for its compact habit of growth and free flowering qualities at a season of the year when flowers are not plentiful. It is moderately tall in growth, though at the same time of an upright, sturdy, and compact character. The leaves are large and of a rich bronzy lustre on the upper surface and crimson beneath. They are more than ordinarily attractive, and of course add to the value of the plant as a decorative specimen, and enhance the beauty of the flowers, which are freely produced, and are large, flat, of a soft, silky, rosy pink colour. The compact habit is chiefly due to its branching freely when it has become fairly established in vigour, and the roots have taken possession of the soil. When a plant commences to flower it continues to do so almost perpetually, if in a suitable temperature for making progress, and the plants have previously been well grown.

B. Gloire de Sceaux (fig. 48), is chiefly propagated from cuttings, which are produced from the older plants after flowering. It is frequently necessary to curtail the tendency of the plant to flower in order to obtain cuttings to provide stock for another season, young plants usually being the better and more vigorous bloomers. The cuttings may be obtained from the young growths which push from the base, and ought to be inserted during this month or early in April if good plants are required. Prepare a light, sandy, open compost of loam, leaf soil, peat, and sand. Place this into 3-inch pots, and insert the cuttings an inch apart around the edges. Stand the pots on a moist base in a brisk bottom heat, and in a top temperature of 65° to 70° . They may be kept fairly close to maintain the cuttings fresh and encourage their rooting, and when this has taken place allow growth to proceed for a time, then take off the tops. If more plants are wanted insert these as cuttings. When the topped plants have pushed fresh growth turn them out of the pots, divide, and pot singly in 3-inch pots, using similar compost with the addition of charcoal crushed fine.

The newly potted plants will require heat and moisture to encourage growth. Water carefully, which means only give light supplies at first. Syringing them is perhaps the best method of supplying moisture in the early stages. The soil being moist when

young succulent growth. After a fair start has been made progress will be remarkably free, and it is desirable to top the growths again, thus securing the foundation of a bushy habit, and obtaining larger plants.

FIG. 48.—BEGONIA GLOIRE DE SCEAUX.

potting, and the pots stood on a moist base, it requires little water to maintain it in the right condition. Accord the plants a light position, but they will be better if kept from direct sunshine, which at this period is likely to be of a scorching character, and too much for the

When it is apparent that the pots are too small or soon will be, preparations must be made for a shift into a larger size. From 3-inch move into 5-inch, this potting taking place in July or August with those rooted earliest. September should be the latest period for

finally potting those rooted in April; 5-inch pots will be the size for the majority of the plants, but a few may have larger pots. Probably, however, the smaller pots may eventually contain the better plants, and, as a rule, when in a medium size they are more useful for decoration.

After June artificial heat is not required, but moist frame treatment ought to be given them. This is secured by standing the plants on a bed of ashes kept damp. Keep the lights on the frame, admitting a little air, and syringe lightly on bright afternoons; also shade from strong sunshine. At the end of September transfer to a greenhouse shelf near the glass, continuing to water carefully. As the natural temperature declines the plants will require artificial heat to maintain them in a healthy condition. Give them a temperature onwards through the winter of 55° to 60° at night.

About December the flowering period commences, and for the next four months it is seldom that any of the plants are devoid of bloom unless they have been cut severely. In one way even the latter is an advantage, as the loss of the bloom causes the production of cuttings, which can be utilised for the next season's stock. Afford a light position for the winter months; the plants are better stood on a moisture-holding base than on dry open shelves, but the structure should be efficiently heated. The watering must be carefully carried out, and this is best done by regular attention in examining the soil, always affording sufficient water of the same temperature as that of the house.—E.

STOPPING VINES.

THE planting of Vines and the formation of Vine borders have been so often dealt with in the *Journal of Horticulture* that I thought a few notes on stopping Vines might be more generally advantageous and useful, especially to those who have not had sufficient practical experience to thoroughly comprehend the correct methods of procedure. There are, I am aware, many systems of regulating the growth of the Vine, and perhaps most of them adopted by some of our best Grape growers vary slightly, but the broader principles are the same. Let us suppose the Vines were purchased in pots, cut down to within 18 inches of the soil, planted in February, and started into growth about the beginning of March, very slowly—in fact, it would be inadvisable to hurry them the first year, though due attention must be given to damping, watering, and airing. As soon as the buds commence to form shoots gradually disbud all except two, one near the top and the other close to the base; the former should be carefully supported if necessary, and the basal shoot ought to be stopped when it has made half a dozen leaves. The latter assists to thicken the old portion of the rod, though many successful growers whom I know retain the leader only.

As the young rod makes progress side shoots will be made which must be stopped—i.e., pinched with the thumb and finger at the first leaf. The young leader will also require stopping at 5 feet, but it must be allowed to form another leader, which should be taken up straight as before; the side shoots from this will not require stopping as above recommended, but should be allowed to run almost wild. The first 5 feet of the new rod which was stopped will thicken considerably, and the basal buds will plump up in grand style, showing how the plant appreciates the treatment to which it has been subjected. In December the Vines should be pruned, the leader to within about 4 feet from the new rod, and the side shoots back to the basal bud. If Grapes are urgently wanted allow two medium-sized bunches to each rod, otherwise do not crop until the following year, as more roots will then be made.

If the young Vines are planted 4 feet apart the shoots should be stopped from two to six leaves past the bunch, but in this respect the grower must be guided by the vigour. If a shoot has the appearance of grossness stop it at two leaves beyond the bunch and pinch the lateral growth at the end of such shoot to one leaf also, but aim at allowing each Vine the full space allotted to it; but never tolerate crowding. The young shoots which form on the side or current year's growth from the spur must always be stopped at the first leaf when quite young, and the Vines should be examined weekly, for if the growths are allowed to get too large a severe check may be given to the Vines. When spurs are formed after the first year's growth they generally have one or two shoots too many on them; retain one only, removing the others promptly.

There are occasions when an extension of lateral growth is decidedly advantageous to all Vines, whether weak or otherwise. For example, a house of Muscat of Alexandria under my charge had been addicted to shanking, so last year I allowed these Vines to make as much lateral growth as possible. At what would be the beginning of the colouring stage had the variety been a black one, and when all fear of shanking had gone, the lateral growth (some of which was 3 yards long), was very gradually removed. The result of this treatment was quite a success, and I am looking hopefully for equally as

good results this year, provided the routine operations of watering, airing, and damping are properly attended to. This fine Grape is much benefited by shading with a treble thickness of fish netting if the panes of glass are of a large size. But as soils and aspects vary so much in different localities, it is necessary to watch carefully throughout the whole period of the Vine's growth to overcome the nearly insuperable difficulties many gardeners have to experience when taking charge of fresh vineries which have been indifferently managed in the past.—A. J.

THE COLOUR OF MARÉCHAL NIEL.

IN answer to "Practice," it is light, and especially sunlight, that influences the colour of this Rose. Shading always increases the yellow, and lessens the red in Roses. I have seen blooms of this Rose in a sunny season on a south wall, not only as pale as the so-called white variety, but even distinctly flushed and stained with red. It is natural, therefore, "to find great variations of colour in blooms upon the same plant, and at the same time," for those which happen to be the most shaded by the foliage or anything else are sure to be of a deeper yellow colour.—W. R. RAILLEM.

CLIMBING ROSES.

THESE are usually most appreciated when in bloom early or before any in the open, and by attending at once to the pruning, tying in or nailing, this will be all in favour of early and abundant flowering. Not pruned at all they soon become unsightly, and of comparatively little value. All must not be treated alike. Hard pruning in the case of such strong growing Noisettes as Maréchal Niel, Bouquet d'Or, W. A. Richardson, L'Idéal, and Aimée Vibert, would lead to the formation of still ranker growth, and few blooms. Thin out the spray, cut away all growth badly placed for training, and only remove the unripened ends prior to securing to the walls and trellises. Strong young trees of Gloire de Dijon and Madame Berard should not be severely pruned, and may well be treated similarly to the Noisettes, but older trees should be freely pruned in order to keep up their vigour. Other Teas, as a rule, ought to be pruned moderately hard, as they cannot well be grown too strongly. Remove much of the spray, and cut back all shoots reserved to within three or four joints of their starting point last spring other than those required for furnishing blank space.—WESTERNER.

PRUNING MARÉCHAL NIEL.

MY remarks on page 92 have been noted by more than one of your correspondents, and they appear to bear me out in this—that until the plants have filled their allotted space with growth it is unwise to prune hard. But it seems to me not so much a question of space to be filled as to which is the better mode to produce superior growth, so that the blooms shall eventually be of fine quality. The example I gave was, I thought, a very good one in favour of little pruning.

After the plants have filled the trellis with growth, what then? Some pruning is, of course, necessary, otherwise a dense thicket of mostly useless stems and branches would follow in a few years, and although I have hitherto had very good results by adopting the plan of a clean sweep of all growths right down to their base after flowering, I may have had better by being more sparing with the knife. Such pruning must severely check the plant above and below; and for a time, as the new shoots start rather weakly, some nursing is required to prevent an attack of mildew, which at pruning time in the case of Maréchal Niel so readily comes.

In the future, then, my idea in the case of young plants is to merely cut away the unripened points of long growths, and entirely remove very weakly ones. Then when the space is filled thin out about half the branches each year to provide a supply of new rods from the base, and the side stems that have produced blooms will be spurred in the whole length of the remainder.

"S. S." asks (page 132), what became of the old shoots on the unpruned plants noted. These were not numerous after the first year's growth, nor had any reached the top of the house on either side. They were left untouched, and the "long clean rods" of last season's growth did not necessarily spring from the base, as it is well known that plants of Maréchal Niel in growing have a habit of pushing out long flowerless shoots in unlooked-for places when all is going on well with the roots below. A hint in the remarks of "W. R. Raillem" (page 120), that it is well when pruning this Rose in a growing state, to do it gradually, is one that would certainly seem worth remembering.—H. S.

ROYAL HORTICULTURAL SOCIETY.

DRILL HALL.—FEBRUARY 27TH.

THE meeting on Tuesday was in all respects a splendid one, the Hall being almost quite full of excellently grown produce. Orchids were magnificently staged by both trade and private growers. Fruits were neither numerous nor particularly meritorious.

FRUIT COMMITTEE.—Present: Philip Crowley, Esq. (in the chair); and Messrs. Jas. H. Veitch, E. Shaw Blaker, W. Poupart, M. Gleeson, G. Kelf, A. Dean, S. Mortimer, G. Miles, W. Bates, G. Reynolds, G. Wythes, R. Balderson, F. Q. Lane, J. Willard, E. Beckett, H. Markham, and G. Bunyard, and the Rev. W. Wilks.

Mr. R. Bullock, gardener to C. Pearce Serocold, Esq., Taplow Hill, Maidenhead, staged a collection of Apples in good condition, which included capital dishes of Cox's Orange Pippin, Blenheim Pippin, Waltham Abbey Seedling, Norfolk Beefing, and Tower of Glamis (silver Banksian medal). Mr. G. Wythes, gardener to the Duke of Northumberland, staged *Vanilla planifolia*, both growth and fruits. Mr. Jas. Hudson, gardener to L. de Rothschild, Esq., Gunnersbury House, sent some ripe fruits of the common Papaw (*Carica papaya*) and received a cultural commendation. A capital dish of Parsnip Tender and True was staged by Mr. E. Beckett, gardener to Lord Aldenham, Elstree, which received a cultural commendation. A number of Apples and a few Pears were before the Committee, but only one secured an award.

FLORAL COMMITTEE.—Present: W. Marshall, Esq. (in the chair); with Messrs. C. T. Drury, O. Thomas, H. B. May, G. Nicholson, G. Reuthe, R. Dean, Wm. Howe, J. Hudson, J. Jennings, R. Fife, R. B. Lowe, C. J. Salter, C. E. Pearson, J. W. Barr, Chas. Jefferies, J. Fraser, G. Gordon, W. H. Lees, Jas. Walker, C. E. Shea, H. J. Cutbush, E. H. Jenkins, H. J. Jones, E. T. Cook and G. Paul.

A table of *Lachenalia Nelsoni* in pots was staged by Mr. W. Allan, gardener to Lord Suffield, Ganton Park. The plants were a mass of golden yellow spikes, and clearly evinced high cultural treatment (silver Banksian medal). Messrs. H. Cannell & Sons, Swanley, arranged a large table of *Cyclamens* in grand condition; the foliage left nothing to be desired, whilst each plant without exception was literally covered with well-developed flowers in every shade known to *Cyclamen* growers. The white, rose and crimson varieties arranged in blocks were particularly effective (silver-gilt Banksian medal).

Mr. H. J. Jones, Ryecroft Nursery, Lewisham, arranged his first group of spring flowers at the Hall, which consisted of *Narcissi* in variety, and included *N. bicolor Horsfieldi*, Emperor, Golden Spur, rugilobus, Sir Watkin, and Henry Irving among others; also a collection of *Hyacinths* in variety, the whole arranged with Palms and Ferns (silver Banksian medal).

Messrs. Barr & Sons, Covent Garden, staged a group of hardy flowers. The *Hellebores* were interesting, and staged in variety. The chief forms were *H. orientalis punctatus*, *H. o. ruberrimus*, *H. o. antiquorum* James Atkins, and *H. o. a. elegans*. Pots of *Narcissi*, such as cyclamineus, *N. coronatus*, and *N. minimus*; also a collection of *Crocuses* and *Cyclamens*. Messrs. Peed & Son, West Norwood, arranged a semicircular group of foliage and flowering plants, which included *Kentias*, *Dracenas*, *Crotons*, *Pandanus*, and *Abutilons* in the foliage section, while *Azaleas indica* and *mollis*, *Begonias*, *Cyclamens*, and *Tulips* were the most prominent in the flowering plants (bronze Flora medal). Messrs. W. Cutbush & Son, Highgate, N., staged a table of spring flowering plants which were most interesting. The *Acacia Drummondii*, *Boronia megastigma*, *Daphne Mezereum*, *Ericas Wilmoreana* and *melanthera*, with *Epacris Lady Pannure* and *Diadem*, formed a unique display arranged with well-fruited plants of *Citrus sinensis*, *Aralias*, Palms, and a front of *Ficus repens* (silver Banksian medal).

From Messrs. T. S. Ware, Ltd., Tottenham, came a collection of rock and alpine flowering plants and bulbs, chief of which were *Iris reticulata purpurea*, *Hyacinthus azureus*, *Galanthus giganteus* and *Whittalli*, also some *Anemones*, *Cyclamens*, and *Saxifragas*. Messrs. Wm. Paul & Son, Waltham Cross, arranged a grand exhibit of *Camellias* in pots, and cut flowers in boxes, while the plants of *Clematis indivisa lobata* imparted a lightness to the exhibit. The large plants staged clearly demonstrate Mr. W. Paul's well-known love for the *Camellia*, though it may be under a cloud as far as public favour is concerned. But on this occasion everyone was compelled to admire the clean healthy plants and their wealth of flowers. The following varieties were well represented—*Imbricata*, *Exquisite*, *Alba Plena*, *Reine des Fleurs*, *Marchioness of Exeter*, *Halleyi*, *Teutonia*, *Mathotiana*, *Lady Hume's Blush*, *Jeffersoni*, *C. M. Hovey*, and *Montironi vera* (gold medal).

The Rose season was opened by Mr. G. Mount, Canterbury, who staged two boxes, and a number of vases of cut blooms. A box of Captain Hayward were in grand form, the colour being bright and the blooms full. Mrs. J. Laing was also of good colour and size, especially for this early date. La France, staged with 18 inches of clear foliage, was also to be admired; as was also Viscountess Folkestone (silver-gilt Banksian medal). Messrs. R. Wallace & Co., Colchester, staged a few baskets of early flowering Irises, *Anemones*, and *Galanthuses*. Four vases of Violets were staged by Mr. G. Nobbs, gardener to her Majesty the Queen, Osborne, and included large bunches of Princess Beatrice, Princess of Wales, Amiral Avellan, and Primavera.

Messrs. Paul & Son, Cheshunt, staged a vase of double white *Lilac Belle de Nancy*, beautiful in colour and nicely perfumed; also Rose Paul's Single White. From Mr. J. Downes, gardener to J. T. Bennett Poë, Esq., Cheshunt, came a beautiful plant of *Agapetes buxifolia* (fig. 49) a hardwooded plant seldom seen. A large group of *Narcissi* in pots was staged by P. Purnell, Esq., Woodland, Streatham Hill, which included some capital examples of Sir Watkin, rugilobus, Emperor, Empress, incomparabilis, and poeticus types (silver Flora medal). Messrs. F. Sander & Co., St. Albans, Herts, staged a new *Camellia* General Hector Macdonald and a double *Azalea* Louis Sander, both of which exhibited points of excellence. Messrs. Jas. Veitch & Sons, Ltd., Chelsea, continue to exhibit their *Rhododendron* hybrids, which are as attractive as ever, the colours being exceedingly bright.

ORCHID COMMITTEE.—Present: J. Gurney Fowler, Esq. (in the chair); and Messrs. Jas. O'Brien, W. Cobb, J. Douglas, H. A. Tracy, H. T. Pitt, W. Thompson, E. Hill, J. Jacques, T. W. Bond, F. J. Thorne,

FIG. 49.—AGAPETES BUXIFOLIA.

J. Wilson Potter, J. T. Gabriel, H. J. Chapman, W. H. Young, H. Little, H. Ballantine, de B. Crawshay, C. J. Lucas, R. B. White, J. Colman, W. H. White, and T. B. Haywood.

The collections of Orchids sent by various growers of repute were of exceptional beauty and interest. Messrs. J. Veitch & Sons, Ltd., Royal Exotic Nursery, Chelsea, contributed a bright and diversified group. The plants were well flowered and effectively arranged. *Dendrobiums* were splendid, and included a fine specimen of *atroviolaceum*, with *Euosmum delicatum*, *Euryalus*, *Cybele elegans*, *rubens grandiflora*, *splendidissimum*, *Wardiano-japonicum*, *nobile*, *Ainsworthi*, *intertextum*, and *splendidissimum grandiflorum*. There were also *Laelia* Mrs. M. Gratrix rosea, *Cypripedium Lathamianum*, *C. calypso*, *Phalaenopsis* Mrs. J. H. Veitch, *Laelia glauca*, *Lycaste costata*, *Sophrolaelia laeta superba*, *Phaio-Calanthe Niobe*, *Epidendrum elegantulum*, and two magnificent varieties of *Laelio-Cattleya callistoglossa* named respectively *superba* and *splendens* (silver Flora medal).

The backbone of the exhibit from Mr. W. H. White, Orchid grower to Sir Trevor Lawrence, Bart, Burford Lodge, Dorking, was found in the beautiful collection of *Dendrobiums*, which comprised *melanodiscus*, *Johnsonianum*, *specio-Kingianum*, *barbatulum puniceum*, *Hilli*, *Clio Burford variety*, *The Pearl*, *Wiganæ xanthochilon*, *nobile*, *Burford variety*, *melanodiscus Dido*, *Treacherianum*, *splendidissimum*, *Dominanum*, *pallens*, *Juno*, *burfordiense*, *chrysodiscus*, and *Luna*. Mr. White sent also a basket of *Cypripedium hirsuto* Sallieri as illus-

trative of the several varieties from the same seedpod; *C. Alice*, *Argo-Morganæ*, insigne seedling, *Chamberlaino-insigne*, *Rothschildo-superbiens*, and *Lebudyannum*, with *Calanthes Ariadne* and *gigas*, *Cochlioda vulcanicum maximum*, *Habenaria bonatea*, several *Masdevallias*, and *Phalenopsis Schilleriana* and *Stuartiana* (silver-gilt Flora medal).

Messrs. B. S. Williams & Son, Upper Holloway, were represented by a small group of Orchids, which had as a centrepiece a grandly flowered example of *Cœlogyne cristata*. *Cymbidium eburneum* was also included, as were *Cypripediums Pitcherianum* Williams' variety, *Boxalli nigrum*, *Euryandrum politum*, *callosum*, *Rothschildianum*, *cœnanthum superbum*, *Lebudyannum villosum*, *Harrisonianum superbum*, *Winnianum*, and *discolor*, with *Playtyclinis glumaceum valida*. Mr. F. W. Thoroughgood, gardener to H. T. Pitt, Esq., Stamford Hill, staged a varied group of Orchids, in which *Dendrobiums*, *Cypripediums*, and *Odontoglossums* were well represented (silver-gilt Flora medal).

Messrs. H. Low & Co., Bush Hill Park, had about a dozen Orchids, including a beautiful variety of *Dendrobium Wardianum*, *D. Brymerianum*, *Cypripedium Charles Richman*, a splendid plant of *Cattleya Trianae alba*, with an example of the typical *C. Trianae*. Messrs. F. Sander & Co., St. Albans, showed *Epidendrum Orphanum*, *Epiphronitis Veitchi*, with several hybrid *Phaius*. Welbore S. Ellis, Esq., Dorking, exhibited some beautiful plants of *Odontoglossums*, with *Cœlogyne cristata alba*, *Dendrobium Lindleyanum*, *Lycaste Skinneri*, and others (silver Banksian medal).

Messrs. J. Cypher & Co., Cheltenham, are too seldom represented at the London shows. On the present occasion they sent *Dendrobiums nobile nobilius*, *Ethel*, *atro-violaceum*, *Cassiope*, *Cybele*, *Ainsworthi* Cypher's variety, *Endocharis splendidissimum*, and *nobile Cooksonianum*, with *Sophranitis grandiflora*, *Miltonia Reezli*, and others (silver Banksian medal). Mr. W. Stevens, gardener to W. Thompson, Esq., Stone, Staffs, sent a splendid collection of *Odontoglossums*, including *sceptrum grandiflorum*, *excellens nobilior*, *e. spectabile*, *Adrianæ Lady Roberts*, *A. rubiginosum*, *A. Lord Roberts*, *crispum* (?) *Golden Gem*, *Wilkeanum concinnum*, *Loochrystiense Kimberley* (silver Flora medal).

Of smaller exhibits Messrs. Charlesworth & Co., Heaton, sent *Epilaelia heatonense*; A. H. Smee, Esq., Carshalton, three varieties of *Cattleya Trianae*; de Barri Crawshay, Esq., Sevenoaks, *Laelia Jongheana* and *L. anceps Dawsoni rosefieldensis*; S. J. Lutwyche, Esq., Beckenham, a seedling *Dendrobium* and *Cypripedium beechense*; T. B. Haywood, Esq., Reigate, a magnificent plant of *Dendrobium splendidissimum grandiflorum* and *D. Virgil*; Baron Schröder, The Dell, Egham, *Laelia Jongheana*; R. I. Measures, Esq., Camberwell, *Cypripedium villosum aureane superbum*; J. Leeman, Esq., Heaton, *Dendrobium nobile virgale* and *Cattleya Trianae West Bank House* variety; Messrs. F. Sander & Co., *Selenipedium Titanum* and *Laelia Jongheana*; G. S. Ball, Esq., Wilmslow, *Zygopetalum Balli*; Col. Shipway, Chiswick, *Cymbidium Traceyanum*; and Lord Rothschild, Tring, *Schomburgkia* species.

CERTIFICATES AND AWARDS OF MERIT.

Agapetes buxifolia (J. Downes).—A very old plant than is comparatively well known (award of merit). (See fig. 49.)

Apple Gubalou (A. Pettigrew).—A handsome variety with indistinct angles. The flesh is firm and very sweet, and is suitable either for dessert or culinary purposes. The deeply set eye is half open, and with reflexing segments. The stalk is very short, and deeply inserted in a round cavity. The skin is yellow, profusely spotted, and dull on the sun side (award of merit).

Camellia General Hector Macdonald (F. Sander & Co.).—A large flowered semi-double variety of a rosy red colour (award of merit).

Cattleya Trianae West Bank House variety (J. Leeman).—A handsome variety, with petals and sepals of soft rose. The lip is crimson on the front lobe with a deep yellow throat (award of merit).

Iris stenophylla (R. Wallace & Co.).—A dwarf-growing singularly beautiful species. The standards are slate blue and the falls deep velvety blue (first-class certificate).

Laelia Edissa (J. Veitch & Sons).—This is from a cross between *L. purpurata* and *L. anceps*. The sepals and petals are soft rose purple, and the lip is rich crimson with a paler edge and a handsome throat (first-class certificate).

Odontoglossum Adrianæ Lord Roberts (W. Stevens).—A beautifully formed flower. The prevailing colour is yellow tinged with green, and there are numerous bright brown blotches and spots. The lip is of a paler shade (award of merit).

Odontoglossum Loochrystiense Kimberley (W. Stevens).—A very beautiful variety, with a general ground colour of soft yellow and small and large brown spots (award of merit).

Primula kewensis (Royal Gardens, Kew).—This is a cross from *floribunda* and *verticillata*, and is extremely floriferous. The flowers are bright yellow (first-class certificate).

Zygopetalum Balli (G. S. Ball).—This is a new species. The sepals are rose carmine with a white base and margins; the petals are of a similar shade, but the colour is not in one mass, but is divided into spots towards the tips. The central portion of the lip deep crimson with a very broad pure white margin (award of merit).

FLOWERING PLANTS FROM SEED.

PENTSTEMONS.

THE Pentstemon is an herbaceous perennial of an attractive character when in bloom, and well suited for growing in a border of choice perennials. Though a perennial it will flower the first season from seed, and it is owing to this fact that it has become more popular as a summer bedding plant. To obtain strong healthy plants which will bloom creditably the first season, it is essential that the seeds be sown early. Though March is rather late to raise from seeds so that flowering plants may be obtained the same season, with a little extra attention in encouraging growth in a moist heat, and plenty of light, so that they may be transplanted early into boxes, good stock will be forthcoming by the end of May. A pan or pot will accommodate sufficient seedlings to fill several boxes when pricked out.

A light compost of loam, leaf soil, and sand should be prepared. Make the surface smooth and fine, moisten, and sow the seeds not too thickly, covering with a thin layer of fine soil. Shade with damp moss or paper until germination ensues, which will soon take place in a temperature of 60°. Accord the seedlings a light position, maintaining the soil moist, and growth will advance rapidly. The next operation must be to transfer the seedlings to boxes. Continue them in the same temperature so as to encourage growth becoming free, then gradually inure to cooler conditions. Plant finally in well dug beds in an open position at the end of May. They will bloom well in early autumn. The details for raising Pentstemons are also applicable to *Petunias*, *Gaillardias*, *Stocks*, *Asters*, *Phlox Drummondii*, *Salpiglossis*, *Scabious* for a summer display, and to *Pansies* and *Violas* for autumn flowering.

SWEET PEAS.

In order to obtain an early display of bloom a number of 4 or 5-inch pots may be three-parts filled with soil of a rich character and five or six seeds sown in each. When the seeds have germinated afford a light position on a shelf for the pots, a cool or only slightly heated structure with a free circulation of air being the best. A garden frame is an admirable place for them when growing, and if not heated cover the glass on cold nights to avoid a check. On every favourable occasion expose fully so that the plants will be thoroughly hardened for planting out in rows late in April. When thus planted affix the sticks down each side, which will render both support and protection. These early rows will afford the first flowers. Successional rows may follow, but the seeds must be sown directly in the position. Stake them early when through the soil with branched sticks. All the choice named varieties had better have the pot treatment, as it is certain to insure good plants, and is economical in seeds. Sweet Peas should this year have special attention given them, as more than ordinary interest will be attached to the flower, seeing that the present year marks the bi-centenary of its introduction.

STOCKS.

Stocks are capable of producing a long succession of flowers, and are showy and fragrant. The season may be commenced by sowing the Ten-weeks varieties, which will come into flower first, the succession being maintained by the Intermediate and Emperor varieties. Ten-weeks Stocks may be sown now, the others three weeks later. Drain some pans, pots, or shallow boxes. Save the rougher parts of the compost to place over the crocks. The soil should consist of loam, leaf soil, and sand, and it is a good plan to practically roast the compost before using in order to destroy insect or fungoid life. The latter often causes trouble when the seedlings are young by taking possession of the tender stems and causing the plants to collapse. The soil, if dried by heating, must afterwards be brought to a moist condition by sprinkling with water and well mixing. Place it in the pans or pots moderately firm and give a gentle watering. When drained sow the seeds, covering lightly with fine compost; they will germinate readily in a temperature of 55° to 60°.

On the appearance of the seedlings place the pans or pots in a lighter position, taking special care not to under or overwater them until the stems become harder, which is encouraged by air and light. This condition being insured, and the plants large enough, prick them out 2 inches apart in boxes. Keep the drainage holes open by crocks laid upon them, and a few between. On these spread a layer of flaky manure, filling with a compost consisting of loam, leaf soil, manure, and sand. Shake the whole firmly down, and prick out the seedlings. Insert the roots straight down in the holes, which ought to be made sufficiently deep for this purpose, and press the soil well round them. Water sparingly at first, but encourage growth in a warm, moist temperature, transferring the plants when established to cooler quarters; slow, steady growth being preferable to rapid advances. Before the plants become too large remove them to a cold frame where they will always receive plenty of light and air freely, and on favourable occasions full exposure during the day, but afford protection at night until safety from frost is past, which will be the end of May. At this time transfer to the flowering positions in good soil of fair depth. Cut the plants out of the boxes with squares of roots and soil attached, sinking them to the lowest leaves.—E. D. S.

[For the excellent illustration of Stock Princess Alice (fig. 50) we are indebted to the courtesy of Messrs. J. Veitch & Sons, Chelsea.]

THE WANDERINGS OF MR. PETER BARR, V.H.M.

(Continued from page 112.)

I VISITED the Falls of Niagara, and I spent two days with Mr. Cameron, who is in charge of Queen Victoria Park on the Canadian side—a fine man and a good botanist. The Falls are shrinking, though some deny it; but I think, with Mr. Cameron, the river will never be as full as it used to be, except when there are floods. The reckless cutting of timber all over the States and Canada has decreased the volume of water in the great rivers and lakes. At Milwaukee I met a Mr. Dunlop, who has been there since early in the forties—a fine old Scotsman, who was a friend of Loudon's, and in conjunction with him laid out a famous garden at Streatham—I forget the name at the moment. Mr. Dunlop confirmed the lowering of the great lakes.

Then I went to Rochester, and called upon Elwanger & Barry. Mr. Barry took me to the parks. I there met John Dunbar, the Assistant Superintendent—a most exceptional man. Being surprised at his work, I asked him where he came from. He had been, amongst other places, at John Laing's, Forest Hill; and was three years under Falconer, when he was at a great man's place near New York. I next went to Albany. Here I found a most remarkable statue to Robert Burns, the Scottish poet, unlike anything of him that has yet appeared. Thence I returned to New York. I was nearly four months on this tour. I then went to Burlington, Vermont, to see what was being done in agriculture, but the ground was frozen hard, so I looked over the indoor work. At Charlotte, Vermont, I met Mr. Pringle, the Mexican botanist, at his cousin's house, Mr. Horsford, of Tomato fame. Journeyed on to Montreal, Quebec, and Ottawa. Here the Government put a sleigh at my service, and I made two visits to the Experimental Farm, where good work is being done.

After Ottawa I spent a month with a cousin, eighty years of age. With an uncle and aunt, and some seven or eight children, he went to Canada fifty-six years ago, so that Paul's and Barr's literally inherit the land. I was never amongst so many Barr's before. Then to Toronto. This is a perfect city, with fine parks, that want more money spending on them. Hamilton is a nice place; London is lovely; Windsor, where John Barr, the writer, came from, is dirty. After calling at Detroit and Chicago, I had four or five days on the train to California.

Visiting places on the way I landed at St. Barbara, and in company with Mr. Dreer, of Philadelphia, spent some days in the private and public gardens. I then took steamer to San Francisco; and passed on to see Carl Parry, at Ukiah, the centre for collected Californian bulbs. After that to Santa Rosa, to see Mr. Burbank, the wizard hybridiser. To reckon up the value of this man's work would mean six months at Santa Rosa. All America have their eyes upon him, and he is doing a great trade in the sale of grafts, which he sells by the foot. He has a nurse tree, on which are 500 grafts. He sows the seed in spring, grafts in winter, and in three seasons he knows his results. I wanted him to carry his knowledge to the Chiswick Conference, but this he could not manage. Then I said, send a paper; and this he promised to do. We visited the seed grounds of Moss and the Californian Nursery Co., at Santa Clara. In California I found the country white with Prune blossom for miles and miles, and still the planting goes on. Once they can cure the Prunes as well as the French the industry in this will be great, and affect the French market.

After this I took shipping on the good ss. "China," March 24th, for Yokohama, via Honolulu. At this last place I spent one day at the museum and the Government gardens, presided over by a Scotsman, reaching Japan 12th April, in time to see the tail end of the Cherry blossom feast. In February the Plum blossom is on; in March and April the Cherry blossom. These are the great spring feasts in Japan.

Nurseries are spread all over Japan, but the two principal are in Yokohama. Boehmer & Co., a European nursery, run by a German, Mr. Ungar; the other a very extensive one, the Japanese Yokohama

Nursery Co. I work between these, as the two are each willing to give me every kind of information I desire. I have been several times to Tokyo and other places. One tour I made to Kobe, calling at Nagoya, a great centre for China goods (porcelain); Osaka, the centre for tree Pæonies, where I described sixty sorts for the Yokohama Nursery Co.; and Kyoto, a great place for ancient Bhudda temples. Nara was once great in temples, but not so much so now. There is the great bronze image of Darbutsu, 53 feet high, in a sitting posture, dating back to 747, when the casting began. Hundreds of tame deer roam about, and take bread from the hands of visitors. Paid to see the sacred dance at one of the temples; and then returned to Yokohama in time to see the spring races, the Emperor being there, who for the first time, at the invitation of the foreign community, drove through the European settlement—a great occasion. The Emperor is a divinity, descending from the sun's eye, and no one head must be higher than the Emperor's, and no peeping Tons allowed; window blinds had to be drawn down, and we had all to stand on the level of the tire of the carriage wheel.

I went north 800 miles to the island of Yego to the capital Sapparo and saw the ancient race of Japan, the Ainu, now fast dying out. In

my northern tour I saw some of the wild Lilies, and all along the railway sometimes whole fields of the species *Iris Kämpferi*. It is said that over a century ago this *Iris* became a favourite with amateurs, and has been cultivated ever since. Now that the Damios, who were the great patrons of horticulture, have been abolished, the flower has gone into interested parties' hands. Thus in Tokyo there are three large collections, and while the plants are in flower the people flock to these places, which for the time are turned into tea gardens, and these visitors drink tea or sake, make poetry on the flowers, and enjoy themselves. Sometimes private theatricals are held; like the Cherry blossom festival, a time of pleasure, but mostly amongst the better class. The Cherry blossom time is a notable occasion with all classes, and a great time to drink sake. A marriage in Japan is celebrated over three cups of sake; the man drinks three cups and the woman three cups in the presence of the members of each family, and the knot is tied.

The culture of dwarfed trees has been a great art for hundreds of years. There is one at the Yokohama nursery of which they have data for 400 years, and they suppose it may be 500 years old. Most of those trees go to America and are killed, so I have drawn up directions how to manage them for the Yokohama Nursery Co., and shall suggest they send one to each of the American

and English newspapers. (See page 492 last vol.). *Lilium rubellum* is a valuable Lily for market men, three to be put in a 5-inch pot.

Here, as in America and Canada, I have met with every attention and kindness. I have sent many Japanese books and pictures to my daughter Agnes, the artist. Somewhere within three weeks I will close up here and move on to China. I may mention I have prepared descriptions for about three hundred varieties of *Iris Kämpferi*, and will prepare cultural directions, as it is a pity that people so often fail with it. The Japs manure both *Iris* and Lilies when they are working at the roots, but not when the top appears above ground. They grow the *Iris* in the Rice fields, and all the time they are growing they are in water. When done flowering the water is drained off. In England they should be grown in beds that can be soaked with water once a week or oftener while growing, and after flowering less water, and about August no more water. The Japs use liquid manure.

The Bermuda Lily not being equal to the demand, a New York syndicate started the industry in Japan. This year about four millions will go to America and Europe, mostly New York and London. The roots, when the demand was made, were collected from the southern islands, and are represented by some six or more varieties, and as the Americans depend upon having the flowers by Easter, for general convenience I have been pressing home upon the Yokohama Nursery Co. the importance of getting rid of all but two sorts. Thus you see I am leaving my impress on Japan in a quiet sort of way.

FIG. 50.—STOCK PRINCESS ALICE.

THE YOUNG GARDENERS' DOMAIN.

PRIMULA SINENSIS.

I THINK Chinese Primulas rank among the most popular and serviceable of winter flowering plants; the variety of colours claims for them general admiration, and it would be difficult to find a substitute for the embellishment of the conservatory at the dull season of the year. If the atmosphere about them is kept dry they continue in bloom for a great length of time. The disadvantage with the singles is they are of little use in a cut state, while the doubles are of unquestioned value.

Where an extended display of flower is required sowings at intervals from February to May should be made, but for ordinary purposes I think the first week in March a good time to commence. A compost of yellow loam and leaf mould in equal parts, with a fair proportion of silver sand, I find good for this purpose. The whole should be thoroughly incorporated and sifted through a moderately fine sieve. Clean, well drained pans or pots may be used, and should be filled to within an inch of the top with the soil. It is a good plan to sprinkle a little sand over the surface and give a good watering prior to sowing. The seeds should be sown as thinly and evenly as possible, after which cover lightly with fine soil, and place a piece of shaded glass over the whole. On a shelf in a greenhouse, where there is a temperature of about 55° to 60° is a good place to stand the receptacles till germination has taken place.

As soon as the seedlings appear gradually inure them to more light and air by raising the cover glass until it can be removed altogether, but a little shade will be found necessary for a time on bright days. When they have developed the third leaf, or can be handled without injury, prick them off into small thumb pots, and replace on the shelf as near the glass as possible. In a few weeks they will be ready for another shift, which should be into 60's. The compost this time need not be sifted, and a rather smaller proportion of sand should be used. A cold frame where the greatest possible amount of light and air can be admitted should be chosen for them after this potting.

When the roots are through the soil their final shift into 48-pots should be given. I consider this size quite large enough. After returning them to the cold frame keep close for two or three days, when root action will have recommenced. The plants should never be potted if the ball of soil, and that to be used, is dry. Firm potting is always necessary for sturdy growths, which is conducive to a grand display of bloom. The flowers should be kept picked off till about the first week in October; the plants will then bloom throughout the winter.—ASPIRANT.

EARLY STRAWBERRIES. (Continued from page 146).

TURNING to the forcing of these plants, shelves erected in Peach houses and vineries are very suitable places, but they should be as near the glass as possible, and not too close to the ventilators, where cold draughts direct on to the plants would be liable to cause a severe check. To maintain a succession of fruits, a hotbed ought to have been made consisting of litter and leaves, in which a number of pots should always be plunged, as then, when one stock has done its work there will be others to follow.

To obtain ripe fruits by the end of February and the beginning of March the plants should be placed in an early vinery about the middle of November, which temperature will be found suitable until the fruits are swelling; then they will require a higher temperature to have them ripe at the time stated. When the plants are taken in the pots should be washed and the drainage examined, as if the latter is not in proper condition the soil may become sodden and sour. Attend to the syringing of the plants mornings and afternoons when the weather is bright to keep pests in check, but this should always be done in time to have the foliage dry at night. When the plants are in flower they will require a drier atmosphere; it will be necessary to brush the blooms daily with a camel's-hair brush or a rabbit's tail about midday to distribute the pollen and to insure a better crop. This is an operation that must be carried out with extreme care, and will be found by young men extremely interesting work.

After the fruits are set they will require thinning, leaving about five fruits on each of the earliest plants, and seven to nine on the later ones. They will now require abundance of water, never allowing the plants to become thoroughly dry; if so they are liable to get red spider, and poor results will ensue; liquid manure should be given once daily. Strawberries in pots are very subject to mildew, and they should be examined carefully at intervals, and if any signs of it appear dust a little flowers of sulphur on the affected parts before the enemy reaches the fruit.

When the fruits are swelling the plants ought to be removed to a temperature of 65° to 70° at night, that is for the early ones. As the fruits show signs of colour discontinue the use of liquid manure and the syringe, and admit a little air at nights if the weather is favourable. When the fruits are about ripe remove the plants to a cooler house that has a temperature of about 55° with plenty of air, as the fruits will keep much longer and be of superior flavour. The varieties to force I will leave for the growers to decide, as there are several to choose from, but my opinion is that Royal Sovereign is one of the best for this purpose.—P. R.

HARDY FRUIT GARDEN.

Spring Planting Strawberries.—Strawberries may be established in spring, though not with the intention of fruiting them the same season, unless the plants can be so moved and planted that the roots are not disturbed in the process. As a rule, however, spring planting does not lend itself to securing a crop the season immediately following, and it is best not to allow the plants to fruit. They may be encouraged to develop the flower stems sufficiently far so that it is known the plants are fruitful in character, but to bear a crop the first season weakens them considerably, for the energies of the plants are devoted to maturing the fruit, whereas they should be directed to building up strong crowns for the succeeding season.

Preparation of the Soil.—A good depth of loamy soil in an open aspect is the most suitable position for Strawberries. Thorough preparation of the ground must be made, either now or previously in the autumn, and the liberal addition of manure of a well-decayed character. In working the land it is desirable to keep the best soil at the surface and the subsoil in its original position. Heavy soil requires lightening by incorporating with it wood ashes and gritty material, which tend to keep it open, while very light soils are improved by the addition of pulverised clay or marl. Also, recently prepared light soils must be well firmed before planting is done. Compression tends to keep in the moisture, and Strawberries root better in firm soil.

Planting.—The planting should be carried out when the weather is favourable and the surface soil dry. As a general rule, the distance between the rows will be 2 feet, placing the plants in the rows 18 inches asunder. Some of the strongest growing varieties may be planted in rows 30 inches apart, the plants 20 inches asunder, but for the majority the former distances are ample. Plants that can be lifted from nursery beds in the same garden or within easy access move with plenty of roots and soil attached and soon become established. Stock, however, which is purchased may have a fair amount of roots, but no soil is adhering, hence more care is necessary in planting. Keep the fibres as fresh as possible, protecting them from sun and air. Should they have become very dry they ought to be thoroughly wetted and plumped up in water previous to planting. The method of planting these should be first to draw a drill, and in the drill form small mounds of soil on which place the plants, spreading out the roots equally, and cover them with fine mould spread carefully upon the fibres from the crown outwards, the latter being level with the surface of the ground. Make the soil firm around the roots.

Varieties.—Strawberries for early crops may consist of Royal Sovereign, Laxton's No. 1, Scarlet Queen, Noble, Vicomtesse Hericart de Thury, and King of the Earlies. Midseason varieties comprise President, Sir J. Paxton, Newton Seedling, Leader, and Monarch. The latest varieties include Elton Pine, Latest of All, Frogmore Late Pine, Jubilee, and Waterloo.

Treatment During Summer.—Frequent attention must be given to the plants during the spring and summer although they are not fruiting. In the first place it is very important to maintain the surface about the plants loose with the Dutch hoe, especially during the prevalence of dry weather. This not only promotes growth but prevents rapid evaporation of moisture from the soil, and keeps down weeds. Runners must also be cut away as fast as they appear, and water will be required during exceptionally dry periods. A light mulching of littery manure during the hottest weather is beneficial, but rich manure is not needed the first season.

Established Strawberries.—*Weeding and Cleaning.*—The remains of the autumn manuring should be raked off and strong weeds forked out. Cut off dead and withered foliage, and hoe between the rows to destroy seedling weeds.

Spring Mulching.—A dressing of moderately fresh manure may be spread between the rows of fruiting plants. As this contains both strawy material and solid manure the latter affords nutriment which will wash into the soil for the plants' benefit, while the strawy matter, becoming bleached and clean by exposure, affords a bed for the ripening fruit later on.

Pruning Cob Nuts and Filberts.—The pruning of Nut bushes is best carried out when the catkins or staminate flowers have shed their pollen, the pistillate blooms being fully open when the pollen began to disperse. The catkin-bearing shoots, when fertilisation has been effected, are not required to remain at full length, hence may be shortened closely back. Wood that bears neither catkins nor pistillate flowers is of an unfruitful character, and may be shortened also, but if sappy and strong remove it entirely. Retain twiggy shoots, these bearing blossom buds at their points. The last year's bearing shoots must be pruned to within half an inch of their base. Thin out crowded spur growths. Where catkins are scarce procure some from any Nut

trees, and hang them among the branches. Remove suckers springing from round the bushes. If more bushes are required to be established plant compact suckers about 2 feet high.

Wall Trees.—Finish the pruning and nailing of all trees upon walls, endeavouring if possible to afford ample room for the branches by removing crowded ones, even if those remaining are situated at greater distances than absolutely essential. It is better that they should be thinly placed than overcrowded. Rank growth of spurs or clumps of spurs is another evil which to some extent may be rectified by the bold removal of every other clump. It is not advisable to practise too much pruning at one operation, but to proceed gradually where cases call for more than ordinary treatment. The removal of old inert soil from over the roots will in some cases be advisable, substituting fresh compost.

FRUIT FORCING.

Cherry House.—Ventilation is an important factor in the cultivation of Cherries under glass. A free circulation of air should pass through the house wherever the temperature exceeds 50°, the amount of air being regulated by the conditions of the external atmosphere. Employ fire heat only to prevent the temperature falling below 50° in the daytime, and to maintain a night temperature of 40° to 45° in the house when the trees are in flower. Attend to fertilising the blossoms. Fumigation must not be resorted to whilst the trees are in flower, but will be necessary as soon as the fruit is set. It is also requisite to watch closely for the appearance of grubs, one kind rolling itself up in the leaves, and can be eradicated by squeezing; but the other encases itself in a sort of web on the under side of the leaves, giving them a scorched appearance, and from these it passes to the clusters of fruit, perforating and destroying them. The only means of extirpation is to examine the trees occasionally and destroy the caterpillars.

Peaches and Nectarines.—*Earliest Forced House.*—The fruit has nearly completed the first swelling, and will soon enter on the stoning process. If the thinning has been properly attended to there will be about one fruit of the larger Peaches to every square foot of trellis covered by the trees. Nectarines and Peaches not of the first size may be left a little closer. There is danger, however, of the fruit falling if too many are left, but this depends greatly on the wood being well ripened and the otherwise healthy condition of the trees. If there be more fruit than specified above remove the smaller. During the stoning process keep the temperature as equable as possible, as a sudden check by draughts of cold air in the daytime and too high a temperature at night may prove disastrous. The night temperature may range from 60° to 65°, but 5° less will be safe in severe weather; 70° to 75° by day with sun heat, and about 65° by artificial means when the atmosphere is cold and the sky overcast. Secure the shoots to the trellis as they advance, keeping those retained to attract the sap to the fruit stopped at the second or third joint. Keep red spider in check by syringing in the morning and afternoon of fine days. If thrips and brown aphides appear fumigate carefully when the foliage is quite dry. For destroying the insects named there are a number of advertised insecticides, all suitable for their respective applications. Afford due supplies of water to inside borders, or if the trees are at all weak liquid manure in a properly diluted and warmed condition.

Second Early Forced House.—Disbud gradually, removing the ill-placed and unnecessary shoots, not reserving too many of the best situated and most desirable, and tie down the growths early, so as to give them the desired inclination, allowing sufficient room for swelling in the ligatures. Thin the fruit by degrees, first removing those on the under side of the branches or otherwise badly placed, but leave those in the best positions for receiving light and air until they indicate by free swelling the need for further reduction, then remove the smaller, and so on until only a few more than are required for the crop are left. Syringe the trees on fine mornings, and ventilate early in favourable weather. The temperature may range from 55° to 60° at night, 60° to 65° by day, ventilating at the latter temperature, and closing the house when the heat is declining, allowing an advance of 5° to 10° from sun heat. Supply water as required, but avoid making the soil very wet at this early stage, for it only induces soft growths.

Houses Started in February.—Trees started early in the month are now in flower. As in many cases there will be more flowers than needed, all those on the under side of the shoots may be removed by drawing the hand the reverse way of the growths, and where the blossoms are closely set they may be still further reduced, especially on the weaker shoots. A night temperature of 50° to 55°, and 55° by day artificially, is suitable, falling 5° on cold nights, ventilating from 50°, as a close atmosphere is fatal to the blossoms, freely at 55°, and allow an advance to 65° from sun heat. Fertilise the flowers in the early part of fine days, either by shaking the trellis or dusting the blossoms with a camel's-hair brush charged with pollen. It is the better plan to pay attention to each individual flower when its pollen is ripe. Cease syringing when the trees are in flower, but the floor and border should be sprinkled morning and afternoon.

Houses to Afford Ripe Fruit in July and August.—These must now be closed, syringing occasionally until the buds show colour, when it should be discontinued. The borders must be brought into a thoroughly moist state by repeated waterings if necessary, supplying liquid manure to weak trees. If the lights have been off during the winter the borders will not require watering until the fruit is set and advanced in swelling.

When the buds are sufficiently advanced, and when there is a superabundance of promise for fruit, all those on the under or back of the shoots may be removed, which will strengthen those that remain and conduce to a good set of fruit. Maintain a temperature of 40° to 45° at night, 50° by day, with a little air, advancing to 65° with sun and full ventilation.

Strawberries in Pots.—The earliest plants are ripening their fruit, and when it changes colour a drier and more freely ventilated atmosphere is desirable, but there must be no sudden change. The temperature for inducing the fruit to swell should be 60° to 65° at night, and 70° to 75° by day, advancing to 85° or more from sun heat. Plants in vineries and Peach houses which are started periodically will afford successional supplies of fruit, there being no need to move the plants except to meet special requirements. Introduce plants to the shelves of late fruit houses, which suit the late forcing varieties.

THE BEE-KEEPER.

CREATING A DEMAND FOR HONEY.

BEE-KEEPERS have sometimes a difficulty in finding a market for their produce, as the competition is much keener than it was a few years ago. Producers, however, have often themselves to blame for this state of affairs. The chief cause is disposing of the produce early in the season at a low price, instead of holding it until a demand arises. Neglect in grading the different samples, and carelessness in the small details of management, the wood of the sections being discoloured with propolis, are also factors towards this undesirable end, while using bottles and jars without any attempt at neatness or uniformity is also an error.

These are a few of the causes why bee-keepers sometimes find their produce a drug in the market. No opportunity should be lost in endeavouring to create a demand for honey. There are several ways in which this may be done. For example, making it known locally that genuine honey may be obtained in the district. This and placing it in suitable packages will usually have the desired effect. Care should be taken that only honey of good quality is offered in this manner; there must be no cause of complaint, and customers will return. It is surprising the quantity that may be disposed of by working on these lines.

We have been induced to make these remarks owing to the complaints sometimes heard from bee-keepers who will not take reasonable trouble to place their produce before the public in the best possible manner. Quite recently we saw some sections of honey which had been sold to a provincial dealer at a cheap rate; some were unsatisfactory, whereas others were really first-class. The wood of many of them was much discoloured, as no attempt had been made to clean it, which would have improved their appearance; nor had they been graded. Had this been done it would have been better for the producer, the retailer, and the consumer. The former would have obtained a better price, the retailer would doubtless have done more trade, and the consumer would be more likely to buy extensively.

TREATMENT OF HONEY.

The manipulation of run honey requires some attention if the best results are to be obtained. Grading the various samples is even more important than when handling comb honey. We have known bee-keepers mix dark and light honey together with the intention of making a good sample. This is a plan not to be recommended, as the result is invariably an inferior sample.

During a favourable season when the honey is obtained from various sources it is not often that any two samples are exactly alike. The honey from field Bees is brown, and should be kept separate from the honey of lighter colour. We prefer to keep a sample of each until the bulk is disposed of. It can then be examined at any time with the knowledge that the stock remaining will be of the same quality. Ripe honey will granulate, and it is interesting to observe that retailers now realise that this is a mark of genuineness. Heat in some form or the other is necessary if it is required to keep the honey in a liquid condition. We have sometimes placed the glass jars of honey in the sun for a few hours, which had the desired effect. The simplest plan, however, is to place the vessel containing the honey in hot water until the whole is dissolved.

If properly treated it will not granulate, and will keep in good condition as long as required. We do not recommend unripe honey to be treated in this manner; although some bee-keepers who are more anxious for quantity than quality extract the honey from the combs before it is ripe. They then endeavour to improve on nature by ripening it artificially by using heat and allowing the moisture to evaporate. This is not a success, and has done much harm to bee-keeping in this country.—AN ENGLISH BEE-KEEPER.

TO CORRESPONDENTS

All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Violets Diseased (J. W.).—The leaves are infested by the Violet mould, *Peronospora Viola*, which has been rather prevalent this season. The fungus mostly attacks plants in frames, and is certainly favoured by a cold and moist atmosphere. The only thing now likely to be of any use is to dust the plants with air-slaked lime after removing the worst infested and withered leaves. This is more effective than wood ashes, which, however, are excellent. Owing to the plants having been kept safe from frost, the atmosphere would become more or less stagnant, and the plants be correspondingly weakened. A free circulation of air greatly tends to render the plants more disease resistant, and also has a deterrent effect on the fungus. Your experience with the few plants in a broken frame that have been frozen hard is very suggestive of the importance of air, they being in good condition and the leaves perfect.

Repotting Camellias (W. G. B.).—Pot them at the beginning of April into pots a size larger; do not give a large shift. Drain the pots to one-third their depth, and place over the drainage the rougher parts of the compost. Prepare a compost of peat two-thirds, turfy loam one-third, with a free admixture of coarse sand. Turn the plants out of the pots, carefully remove the drainage, and pick away the old soil from between the roots with a pointed piece of wood, being careful not to injure the roots. Pot rather firmly, but not very hard, and with the collar of the plant slightly elevated in the centre of the pot. In potting be sure no vacant space is left between the ball and the sides of the pot. The soil should be worked down with a flat piece of wood, and a gentle tapping of the pot on the bench will help to fix the soil and fill cavities.

Rooting Rose Cuttings (W. H. R.).—Probably the easiest and most certain method for amateurs to root Rose cuttings is by inserting them in sandy soil in the open ground towards the end of October. Trenches are cut for them, much as if preparing for Box edging, some sand being placed in and the cuttings pressed down into it till only one or two buds are above the level of the ground. The soil is then returned, trodden firmly against them, and a sprinkling of sand spread on the surface round the cuttings and well watered to exclude air. The cuttings are made from firm portions of the wood made during the summer, not soft growths, and may be from 6 to 8 inches in length. There is a possibility of a few rooting if several are inserted now in the manner indicated, but the autumn is a much better time for the work. If you insert any, remember that not more than an inch in length of each must be above ground, the remainder within it. Cuttings will also root in August, either outdoors or in a frame, and young shoots of Roses root in warm propagating cases in spring in charge of expert propagators.

Bryophyllum calycinum (W. Raby).—*Bryophyllum calycinum* is remarkable in producing young plants from very conspicuous leaf buds on the margins of the leaves when the latter are laid down on a damp surface in a warm atmosphere. It grows 2 to 3 feet high, and is an evergreen succulent shrub, of no value but interesting as a curiosity. Stove treatment suits it best, growing it in good loam in a temperature of 65°.

Soil for a Vine Border (B. R.).—There is nothing better than the top 4 or 5 inches of a pasture—that is, soil full of the fibrous roots of grasses. Unless the subsoil is naturally porous, put in a foot of rubble, and have a drain laid through it to conduct the water away, covering the stony rubble with turves, grass downwards; then make the border 2½ feet deep. A barrowful of old lime rubbish, and the same of wood ashes to ten or twelve of the turfy soil, would be a good addition, but the Vines would grow well in the loam alone if sound, not very sandy or of a strong clayey nature. A border 3 feet wide is sufficient the first year, adding to the width subsequently. Tread the soil rather firmly, but not hard, and it must not be very wet when this is done. Mix no manure with the turf, but spread some on the surface after the Vines are planted.

Carnation Leaves Diseased (A. T. N.).—Your specimens were considerably delayed owing to misdirection. The leaves are infested by the fairy-ring spot fungus (*Heterosporium echinulatum*). The common name was suggested by Mr. W. G. Smith, from the circumstance that the growth of the fungus from the centre of the spot is centrifugal, and the dark colour is apt to be arranged in concentric lines or rings, representing a miniature fairy ring. The fungus was first described by the Rev. M. J. Berkeley many years ago. The spores are brown in colour, and when produced in great abundance, as in your specimen, together with the threads, darken the spot upon the leaf, and the spot then possesses different shades of colour, according to the number of spores produced. The fungus is, to a great extent, induced by a damp stagnant atmosphere, which facilitates its development from the spores. The plant should be sprayed with a solution of permanganate of potash, or, if you have not a sprayer, sponge the leaves carefully with the solution. It may be necessary to repeat the dressing, giving the plant plenty of air, but not a very arid, yet comparatively dry condition of the atmosphere.

Propagating Indiarubber Plant (Amateur).—If you can command a bottom heat of 85° to 90° you can easily root the top of your Indiarubber Plant. Cut off the head about 6 or 8 inches long, remove one or two of the bottom leaves, and insert in a 4-inch pot in a compost of loam, sand, and leaf soil. Steady the cutting with a small stake. Plunge the pot in the bottom heat, surrounding it with cocoa-nut fibre refuse kept moist. The other portions of the stem having healthy green leaves may be cut into what are termed eyes with a leaf attached, each of which will form a fresh plant. The method of preparing these is as follows:—Cut out that portion of the stem containing the eye and its accompanying leaf. This is done by inserting the knife just above the bud, passing it down the centre of the stem behind the eye or bud, and out just below it. Each of these is secured to a short stick, which inserted in the pot keeps the bud steady, and affords support for the leaf, which should be tied or coiled round it. Three-inch pots and some sandy compost are prepared. The pots are filled with this, and each eye placed firmly in the centre. Plunge them to the rim in cocoa-nut fibre refuse in a propagating frame with a bottom heat of 90°, where they must remain until the eyes start into growth. When both eyes and top cuttings commence growing bottom heat is not absolutely essential, but they must have top heat of 65° to 70° in order to bring them on properly.

Names of Fruits.—Notice.—We have pleasure in naming good typical fruits (when the names are discoverable) for the convenience of regular subscribers, who are the growers of such fruit, and not collectors of specimens from non-subscribers. This latter procedure is wholly irregular, and we trust that none of our readers will allow themselves to be made the mediums in infringing our rules. Special attention is directed to the following decision, the object of which is to discourage the growth of inferior and promote the culture of superior varieties. In consequence of the large number of worthless *Apples* and *Pears* sent to this office to be named, it has been decided to name only specimens and varieties of approved merit, and to reject the inferior, which are not worth sending or growing. The names and addresses of senders of fruits or flowers to be named must in all cases be enclosed with the specimens, whether letters referring to the fruit are sent by post or not. The names are not necessarily required for publication, initials sufficing for that. Only six specimens can be named at once, and any beyond that number cannot be preserved. They should be sent on the first indication of change towards ripening. *Dessert Pears* cannot be named in a hard green state. The practice of pinning numbers to the eyes of the fruits tends to destroy one of the most characteristic features and increases the difficulty of identification. When *Plums* are sent to be named young wood of the trees should accompany them. Leaves of the trees are necessary with *Peaches* and *Nectarines*, with information as to whether the flowers are large or small. (R. W.).—1, Cox's Orange Pippin; 2, Blenheim Pippin; 3, Gooseberry Pippin; 4, Wadhurst Pippin; the Pear is Catillac. (J. W. W.).—1, Reinette de Canada; 2, Newton Wonder; 3, Wormsley Pippin; 4, Court Pendu Plat; 5 and 6, unrecognisable. (W. P. F.).—1, Lord

Derby; 2, Norfolk Stone Pippin; 3, Minchnll Crab; 4, Dutch Mignonette; 5, Braddick's Nonpareil; 6, Northern Greening. (G. H. F.).—1, Dnmelow's Seedling, known also as Wellington and Normanton Wonder; 2, Bramley's Seedling; 3, Lord Derby; 4, Winter Hawthornden; 5, unknown and worthless; 6, Lane's Prince Albert.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (S. R. G.).—*Leucadendron argenteum*, the Silver Tree. (P. S.).—1, *Adiantum amabile*; 2, *A. pubescens*; 3, *A. cuneatum grandiceps*. (O. C.).—1, *Eurya latifolia variegata*; 2, *Coprosma Baueriana variegata*; 3, *Euonymus radicans variegata*; 4, *Ruscus hypophyllum*; 5, *Eleagnus variegatus*. (T. V. W.).—1, *Hedychium Gardnerianum*; 2, *Bambusa Fortunei*; 3, *Dendrobium Phalanopsis Schröderianum*; 4, *D. nobile*. (*Inquirer*).—Possibly a form of *Phalanopsis Stuartiana*. (A. E.).—*Restio subverticillata*.

FARMING BY THE BOOK.

THE spread of knowledge in the country villages has been comparatively slow, but with very great improvement in the management and general efficiency of the village schools we have entered upon an era of greater knowledge—and better still, of greater desire for knowledge. Will farmers leave all such ambition to the rising generation; or will they bestir themselves, put aside all old-fashioned and absurd prejudices, and try to farm not only in a scientific manner, but in obedience to the rules of arithmetic as displayed in reliable statistics?

In most modern large establishments a record is kept of the work turned out, and the profit made by every machine, loom, or engine. As soon as it is found that a certain section of the business is not paying its way strict inquiry is made, and either improvements are instituted, with a view to producing a better result, or the machine is discarded, to make room for one which gives better promise of success.

How many farmers who are not large milk producers take any trouble to test the productiveness and profit of their dairy cattle? How many are there who weigh their feeding cattle every week, and are thus enabled to judge when the animals are paying for their food, and when they are not? Some horses will do more work than others, and with less food. These animals should be carefully cherished, for good horses and good men are not plentiful, and when found should be made a note of. Farmers spend large amounts of money in cakes and manures, but they too often look upon such things as necessities because their neighbours do the same; they take things too much as granted, and do not ask sufficient questions of themselves as to the reasons for the profit or want of profit on a certain crop. Absence of care and observation in such matters has much to do with want of success in making agricultural ends meet as things are now, for with expenses increasing and prices of produce standing still, if not declining, the balancing of the account is no easy matter.

One of the great drawbacks of farming is the great length of time which is occupied by so many of its operations. It therefore appears to be the more necessary to keep a close watch on those sections of farm management where defects may be early remedied.

When a cow by monthly tests is found to be unprofitable, why keep her for dairy purposes any longer? at any rate she should not be retained in the breeding herd, unless her offspring are likely to make

a paying price as pedigree stock. There are thousands of cows being milked at the present time (on British farms) which do not pay for their keep, and in many cases where several cows are kept on one farm, the farmer or his wife, even if they milk the cows themselves, have very vague ideas as to the actual butter return of the several animals. The results of tests of the produce of individual cows both in England and in the United States have been very startling, and in many cases have led to the discarding of favourites and the advancement of bovine Cinderellas to the vacant stalls.

Much of the misconception as to the value of dairy cattle is traceable to the hands who do the milking. Many of the best butter cows are what is called "hard to milk." The milk does not come down readily, and especially the stoppings which generally contain the largest proportion of fat. It is too often the interest of the milkman or maid to neglect such a cow and to give a high character to one which lets the milk down easily and gives a fair quantity though of very poor quality. The milk from the two is mixed, and the owner is deceived as to the capacity of his animals; the only way to obviate such a result is a careful test every month under personal supervision.

An accurate knowledge of the amount of money expended in labour on the several crops of the farm is indispensable if the farmer is to be quite certain where his profit comes from, or to know the real cause of his losses. For instance, the Potato crop when successful is a profitable one, but it demands a large expenditure of labour, often more than is sufficiently realised, and if an exact record were kept of the daily occupation of each farm hand, showing in what way his or her time had been spent, it would not be difficult to arrive at a fairly accurate estimate of the cost of producing any crop. By such means the returns from such a speculative crop as the Potato throughout a series of years could be balanced up, the loss deducted from the profit, and the net value of the crop be ascertained.

The same system should apply to the Carrot and Celery crops, which are of an equally speculative nature. Then there is the food consumed by the cattle, sheep, and poultry! Unless the food, whether purchased or of home production, is charged to the particular variety of live stock which consumes it, how is the farmer to know which stock pays him best?

It is the practice on thousands of farms to sell the Wheat and Barley after being properly dressed, but to give no credit to the grain crops for the tail corn which is ground up for the pigs or used by the housewife for the hens. Even small shrivelled grain has its value in £ s. d., and when valued should be paid for by the department consuming it.

The practical begging of good and useful food for pigs and poultry without the same being taken into account properly is often the cause of very mistaken ideas as to the profitability of these two kinds of farm stock. The gross return from such sources may appear to be all profit and highly satisfactory, but tail corn and offal Potatoes possess a saleable value, and ought to be accounted for.

We do not suggest that a balance should be struck every year as between the several products of the farm, but that such records ought to be kept that, when any item is in a doubtful position, and it is thought desirable, means may be available to solve the doubtful question.

WORK ON THE HOME FARM.

Professor Wrightson, writing for the "Agricultural Gazette," has started a very interesting discussion on the cost of keep of farm horses, one point in dispute being whether attendance to the horse and feeding should be charged to the keep of the horse or the labour bill. The Professor says that attendance to the horse cannot be dissociated from the labour bill, and we quite agree with him; but we would go further, and charge the whole maintenance of the horse to the labour account; for to what purpose is the horse kept except for purposes of labour? in fact, what man cannot do the horse or steam power is introduced to perform, and where the horse is not made full use of for purposes of cultivation the bill for manual labour is proportionately excessive. The labour bill should include all charges for manual, horse, or steam power.

The heavy fall of snow last week, followed as it has been by heavy

rains, has left the country in a parlous state. Thousands of acres of land are under water, and farm work is at a standstill. Turnips are all finished, or we hardly dare say what the condition of a Turnip fold would now be. During the blizzard hundreds of sheep were reeked up with snow, and had to be dug out.

Every farmer we speak to has finished all his roots except Mangold, and we see waggonloads of sheep going to market, the empty waggons returning with cake for the animals left in the "wilderness." During an experience of thirty-two years we have never seen anything so like a Turnip famine before.

What is worse is the bad state of the young Clover plants; the only well-set fields we have heard of are on strong land very early sown. Here we have a hint for next season; but farmers are so afraid of harvesting difficulties that they are chary of early sowing. Does the string-binder enter into their calculations here? If so it has much to answer for.

It appears, from a statement in the "Dublin Farmers' Gazette," that a new disease has been discovered among Potatoes. It is termed the yellow blight or root-rot disease. Yellow blotches appear on the leaves, occasioned by the interception of nutriment by the fungus in the stems and roots. We shall probably hear more of this new disease.

We hear that the farmers of the United States are about to set us an example in the way of combination on a large scale. Efforts, we are told, are being made to induce both Wheat and Maize growers to form numerous combinations among themselves for the purpose of building and controlling elevators and doing their own commission work.—("Agricultural Economist.")

RECORDS OF THE DAIRY HERD.—On all well conducted farms where milk is produced, one point always seen to is the keeping of an accurate record of each animal's milk-producing powers. In some instances each cow's milk is measured, and the quantity recorded, or more often it is weighed. Now the latter system may be considered much preferable, as being decidedly more accurate, for, as is well known, good milkers, by reason of the fast flow of milk into the pail, cause a head or froth to collect on the surface, which very much interferes with measuring; therefore to weigh is the better plan. On most farms visited where the milk is weighed the ordinary weighing machine (as used for weighing cake, corn and wool) also answers the purpose for milk, a special bucket (previously weighed) standing on the machine. The milker empties each cow's yield separately into this, and records the weight, deducting from each of these the known weight of the pail.—("Farmer and Stock-breeder.")

CATTLE FOODS.—Oat chaff is better than straw, is relished by cattle, and may be used raw, mixed, or boiled. Oat straw is a most useful food, containing large quantities of starch and digestible fibre, and ought to be better taken care of than it usually is. Used with 8 lbs. or 10 lbs. of linseed cake, or 14 lbs. to 16 lbs. of grain or bran, cattle of 1000 lbs. will get quite fat on it. Compared with other foods, good Oat straw is worth 35s. to 40s. per ton for feeding, while for manure it is not worth 5s. per ton. The farmer who wastes it in litter or otherwise loses 30s. to 35s. per ton. Wheat and Barley straw are useful, although inferior to and less relished than Oat straw. Turnips are relished by all cattle, and, where possible, it is a good plan to wash and pulp them, and to add to the pulp the extra food to be given. The washing clears the roots of superfluous mud and sand, which, when in quantity, induce irritation of the bowels and scouring, and pulped Turnips are relished, and save young beasts the labour and pain of cutting the roots when shedding the incisor teeth. Cattle from eighteen to twenty-four months are, says a writer in an agricultural contemporary, difficult to make fat with Swede Turnips, unless these are either sliced or pulped, and with water power available and proper arrangements the extra labour involved is insignificant.

YEW TREE POISONING AND HOW TO TREAT IT.—It is during weather such as the present, when snow is on the ground, and animals are unable to obtain the natural green food upon which they so largely subsist when allowed an outrun, that the risk of poisoning from the consumption of the leaves of the Yew tree, and other poisonous plants, becomes specially pronounced. It is well known that animals which, under ordinary circumstances, would pass by a Yew tree without touching it, very often commence nibbling at its tempting green leaves when deprived of their ordinary green food in the shape of grass. Wherever such trees are growing in the neighbourhood of places where cattle are kept, special precaution should be taken to guard against the animals getting access to them while snow is on the ground. There is still much uncertainty regarding the manner in which the Yew tree poison acts, but it is well established that the leaves or twigs are specially dangerous when taken on empty stomachs, and that they are also much more dangerous in a semi-withered state than if consumed when quite green or in an actively growing condition. In case of an accident through which an animal may have obtained access to a plantation or lawn and partaken of the leaves of Yew trees growing thereon, the best course of treatment is to administer at once about two glasses (say four ounces) spirits of ammonia, and half a pint of brandy in a quart of linseed or flour mucilage.—("Farmers' Gazette.")

BARR'S SEEDS

OF FINEST SELECTED STRAINS AND TESTED GROWTH

NOVELTIES & SPECIALITIES FOR 1900.

Barr's Golden Wax-Pod Dwarf Butter Bean; the fleshy pale yellow pods run to 8 in. long, are stringless, and of delicate flavour; it is a marvellous cropper and very early. Per pint, 1/9; per quart, 3/6.

Barr's Lightning Runner Bean, a remarkably prolific Runner, and the earliest of all, bearing numerous heavy clusters of long fleshy pods of a fine delicate flavour; a valuable acquisition. Per quart, 2/6.

Barr's Covent Garden Beet, dark crimson flesh, fine flavour, medium size. Per packet 6d.; per oz., 1/3.

Barr's Hardy Winter White Broccoli, a magnificent Broccoli; should be sown from end of March to May for a succession. Per packet, 1/-; per oz., 2/6.

Barr's Little Queen Cabbage, of delicate flavour; highly recommended. Per packet, 6d.; per oz., 1/6.

Barr's New Intermediate Carrot, superior medium long Carrot, of a rich red colour and fine cooking properties. Per packet, 4d.; per oz., 10d.

Barr's Champion Solid White Celery, solid and sweet, remaining long in condition. Per packet, 1/- and 2/6.

Barr's Paragon Cabbage Lettuce, light green, leaves smooth and succulent, medium size, all heart, sweet and tender. Per packet, 1/-; per oz., 2/6.

Barr's Scarlet Perfection Radish, an extra-fine, very early, short-topped, turnip-shaped Radish; colour, rich scarlet; flesh white, mild, and crisp. Per oz., 8d.

Barr's Early Ruby Tomato, solid, deep-red fruit of fine form and medium size, abundant cropper and very early. Per packet, 1/-.

BARR'S SEED GUIDE contains a Select List of the best Vegetables and the most beautiful Flowers for Garden and Greenhouse. It is full of Practical Hints, and will be found invaluable to Gardeners, Amateurs, and Exhibitors. Sent free on application.

CHRYSANTHEMUMS UP TO DATE.

IT is now two years since I had the pleasure of conducting an election of Japanese and incurred Chrysanthemums for the pages of the *Journal of Horticulture*. Since that time the increase in the number of varieties is large, especially in the Japanese section, as the result of this audit will prove. There has been, too, an advance in the incurred section, thanks to the deep interest taken in hybridising for the increase of variety, form, and colour, not only by foreign raisers but by enthusiasts at home. That the publication of such a list of desirable varieties in both sections by experts cannot fail to be of interest to all lovers of the autumn queen and very useful to beginners.

For amateurs especially such an audit must be valuable, as it is difficult for them to make up a collection of varieties in a limited space. It is also pleasing to learn that this audit of up-to-date varieties is highly interesting to cultivators in Australia and New Zealand, where Chrysanthemum culture is rapidly on the increase. As in 1898, thirty-three electors have kindly taken part in the present audit. To them my thanks are due for their co-operation, and also to Mr. James Threlfall, head gardener at Rainford Hall, St. Helens, especially for aid in the tabulation of the returns.

A few remarks on individual varieties and their position in the audit may be interesting. As in 1897, several varieties tied for the 'premier position. There are certain standard sorts that are of such high quality on the exhibition table, that they cannot be omitted by the electors, hence the great number receiving an equal share of votes. Who, I would ask, could leave out of a list of even two dozen sorts the three members of the Carnot family? In addition to these named, Phœbus and Mons. Chenon de Léché are also at the head of the poll in the same way that they were in the last election. Mrs. White Popham, a variety not once named in the last audit, now ties with five others for premier place. The variety is of English origin and must be regarded as a monster. Here, then, is an unmistakeable instance of the general love for size in Chrysanthemum blooms.

No. 2684.—VOL. CII., OLD SERIES.

No less than six tie for the third position; all with one exception were included in the last election. Miss Nellie Pockett is an Australian raised variety sent over two seasons ago, and its rapid progress forms a good estimate of its quality. Those sterling varieties Vivian Morel and Charles Davis still maintain a high position, and rightly so, as they possess all the characteristics of high quality blooms combined with an ideal habit of growth. Edwin Molyneux retains a remarkable hold upon cultivators and the public alike, despite its fourteen years of hard toil and wear. No variety yet can equal it in point of colour, although many seedlings have been raised from it. The position occupied by Mrs. Barkley is a proof of how cultivators seize upon sterling novelties, and must be very gratifying to the raiser, Mr. Weeks.

French seedlings have not been quite so successful of late, as with the exception of Madame Carnot, Phœbus, and Mons. Chenon de Léché we do not find any occupation in the list until we get to Le Grand Dragon, a variety which will not, in my opinion, have a very long stay as a leading sort.

R. Hooper Pearson, with its magnificent yellow colouring, could not fail to receive considerable support, as it does with twenty-eight votes. Etoile de Lyon, once so popular, fails to receive more than seven marks, with Col. W. B. Smith one less. Mdlle. Thérèse Rey cannot find more than four supporters although once so popular. This latter instance is a plain proof that size is an important factor in exhibition Chrysanthemums. No less than seventy-one varieties are named only once, which is a striking illustration of the wide range of choice required by the electors. The fact of there being but one mention of hairy or hirsute varieties—Hairy Wonder—amongst the whole 231 varieties, is a sufficient proof of the want of popularity of this section.

I think that it will be admitted that the selection of sixty varieties does not contain a single variety that can honestly be termed "coarse." The bulk of the varieties are remarkable for their "build," possessing much depth and breadth, with, in the main, a plentiful supply of semi-drooping florets.

VOTES FOR THE BEST SIXTY JAPANESE.

33	Madame Carnot	16	H. J. Jones

231 varieties.

INCURVED VARIETIES.

In the selection of incurved varieties the reader will be struck by the decline of the Queen family in public favour. In the present instance the selection includes five varieties of this type. Even then only twenty-three votes are given for Empress of India and John Lambert cut of a total of thirty electors in the section. In the last election seven varieties of the Queen family occupied a place in the selected thirty-six, Empress of India heading the list with a total of thirty votes. Since that time great changes have occurred in the incurved section. The older type of flower has declined entirely, owing in my opinion to a decay of constitution. C. H. Curtis, as was to be expected, heads the list. Duchess of Fife still maintains its position as one of the leading varieties, while Globe d'Or has improved its place.

Madame Ferlat, a somewhat new French-raised variety, takes quite a leading position. Princess of Wales, although given a good position by the electors, has not during the last two seasons been seen in anything like its form of say ten years since. This type, once a favourite, is, I fear, gradually weakening. The once popular

Prince Alfred cannot at the present moment command more than five supporters; while the much vaunted Mons. R. Bahuant receives one mark less. Princess Teck, Hero of Stoke Newington, and Lady Dorothy are mentioned twice each, while Baron Beust, Refulgence, and Barbara, a trio of favourites twenty years since, are only once named in a selection of no less than 126 varieties. Although so large a number are quoted it cannot be said that many of them will be heard of again in any degree of prominence; they are in my opinion of too "rough" a character to please the true florist.

VOTES FOR BEST THIRTY-SIX INCURVED.

30	C. H. Curtis	4	Mrs. R. King

126 varieties

TWELVE NEW JAPANESE.

The enumeration of new varieties of Chrysanthemums is always interesting, as it reveals peculiarities of selection. To obtain twelve of the most popular eighty-eight sorts are given. Florence Molyneux heads the list by four votes, Madame R. Cadbury following with sixteen. Yellows as usual preponderate; as many as five are named, while only three white flowered varieties are included. Here again English raised sorts are in the ascendant, the whole dozen having been produced at home. No less than forty secure one vote each. In this latter the number is much increased by the inclusion of varieties not strictly new, some of them having been before the public certainly three seasons.

At one time it was said that the type known as Japanese incurved was unduly favoured. This assertion cannot now be supported, as there is a preponderance of varieties of a semi-drooping habit of floret. For vase decoration it cannot be said that the former are better suited than the latter type, as they possess all the characteristics necessary to obtain a pleasing effect either when cut with long or short stems.—EDWIN MOLYNEUX.

HARDY BAMBOOS.

It is doubtful whether any other class of plants has risen so rapidly in public favour as this. Ten years ago a few species only were grown, and the gardens containing them were few and far between. Now many of our up-to-date gardens contain large collections, and, judging from the number of plants seen in nurseries where before a Bamboo was rarely if ever found, the demand keeps steadily increasing. That the Bamboo well deserves its popularity is very evident, for it has introduced into gardens quite a new feature, and one which adapts itself admirably to the requirements of modern horticulture. Contrasted with the old style of evergreen shrubbery—stiff and formal with its mixture of Aucuba, Laurel, Box, Yew, and Privet—a group of Bamboos shows to great advantage, the light and graceful appearance of the long arching shoots, clothed with dainty, light green leaves, producing an effect surpassed by no foliage tree or shrub, and equalled, possibly, only by the elegant, wand-like shoots of the Weeping Willow.

The honour of bringing these plants into such prominence lies, to a great extent, with Kew and Mr. Freeman-Mitford, for, although a few species have been grown in some—particularly Cornish—gardens for a long period, nothing had been done in the way of forming a really representative collection until the authorities at Kew and the above mentioned gentleman took the matter in hand. At Kew a collection of hardy Bamboos has been grown outside for a dozen years or more, but it is only eight years since the subject was taken up in real earnest. At that time the number of hardy species obtainable was

very limited, and the nomenclature bad, but plenty of energy was put into the matter, and now the collection is as representative a one as it is possible to get, while the naming is as near perfection as it can be without having flowering specimens.

Altogether about forty-five species and varieties are grown in the open air at Kew. Of these about five are scarcely hardy enough to be recommended for general cultivation, though they are quite at home in the genial climate of the south-western counties. The remainder are perfectly hardy, having stood the severe test of 1895 without injury. The number of species and varieties alluded to are confined to three genera, as follows:—*Arundinaria*, seventeen species and three varieties; *Bambusa*, eight species; *Phyllostachys*, ten species and one variety. In addition to these there are a few others that are not yet developed sufficiently to allow of their correct names being determined, or have not been tested as to hardiness.

Japan is the home of the majority, twenty-nine species coming from that country. China gives us five, the temperate Himalayas four, and North America one, while the countries of several species are doubtful. The Himalayan species are the tenderest, and should only be planted in places where very severe frost is unknown; about London they are cut to the ground line by sharp frost, but grow again during the following summer.

To select a few and say they are the best would be misleading, for all have their special charms, which show to advantage when contrasted with one another. The straight 15 feet stems of *Arundinaria Simoni*, with thick tufts of side branches; the graceful arching shoots of *A. nitida*, with small, elegant, pale green leaves; the large handsome foliage of *Bambusa palmata* and *tesselata*; the elegant leafy shoots of the various *Phyllostachys*; the golden stems of *P. Castillonis*, with a bright green channel between the nodes; the rich green carpet formed by the dwarf growing *Arundinaria pumila* and *Bambusa pygmaea*, or the variegated *A. Fortunei*, have each their own form of beauty, which to be fully appreciated must be seen.

At Kew a garden is formed of Bamboos and kindred plants, and this appears to be the style of planting adopted by most people when making a collection. The method has much to recommend it, for, in addition to the beauty of each species being enhanced by the contrast with its neighbour, it is much easier to give them the few special attentions they require than when they are scattered about.

When selecting a site for the formation of a Bamboo garden special attention should be given to shelter, for, although perfectly hardy, the leaves are quickly turned brown if exposed to a cutting north or east wind; a cold, cutting wind without frost will do more damage than 25° of frost without wind. Provided the soil is good its consistency makes little difference, stiff clayey loam and light black soil answering equally well. If the soil is naturally poor it should be enriched by a good dressing of leaves and cow manure when being trenched. It is a very necessary item that water should be within easy distance, for in a dry summer abundance of water will have to be given if the plants are to be kept in good health.

At Orwell Park, Ipswich, Bamboos are very effectively planted in grass on the sloping banks of a stream. The soil is rich and spongy, and the plants naturalise very quickly, suckers running about and springing up in all directions. The value of the Bamboo for planting in close proximity with water is well shown at Gunnersbury House, where a good collection has been formed along one side of the lake. In such places as the two mentioned it is a very easy matter to give plenty of water with little expense. Although collections grown together are to be recommended, isolated specimens of such kinds as *P. viridi-glaucescens*, *P. mitis*, *Arundinaria japonica*, *A. Simoni* come in admirably if given suitable places. It is a mistake to have Bamboos in too conspicuous a position, for they take on a decidedly rusty appearance for two months, at a time when other plants are at their best—i.e., from the middle of March until the middle of May; this disadvantage can, however, largely be overcome by judicious planting.

By far the best time to plant is May, when growth is commencing. If plants are received in winter, it is advisable to pot them and stand in a greenhouse until May. If they are imported from Japan they ought to be potted and kept indoors until growth is active. When established out of doors it is a good plan to top-dress with leaves and cow manure early in summer, and thin out a number of the oldest branches annually. Division is the best means of propagation; each little bit with roots will quickly form a good plant if planted in soil containing plenty of decayed leaves.

Intending planters will do well to pay a visit to Kew before deciding on a selection, for by seeing them growing a much better idea of their respective virtues can be obtained than by long written descriptions. In the Kew "Hand List of Hardy Trees and Shrubs" the Japanese names, which are found in Japanese catalogues, are given as synonyms of the correct scientific names, so making straight what was at one time a decidedly crooked path.—W. D.

LÆLIA EDISSA

At the Drill Hall on the 27th ult., there was a magnificent display of Orchids, and the contributors included both amateur and professional specialists. An exceptionally large number was placed before the Orchid Committee with a view to special awards, but this body was not easily pleased, and only a very few were thus honoured. Amongst them was *Lælia Edissa*, which was exhibited by Messrs. Jas. Veitch & Sons, Ltd., Royal Exotic Nursery, Chelsea; to this a first-class certificate was recommended. *L. Edissa* (fig. 51) is said to be the result of a cross between *L. anceps* and *L. purpurata*, the former being the seed-bearing parent. In shape the newcomer resembles the first named. The sepals and petals are soft lilac purple, while the handsome lip is rich crimson with a purple suffusion and a paler margin.

REPOTTING ORCHIDS.

Careful Orchid growers do not make a special time for repotting, but all through the year give new compost to various plants as they need it. But February and two succeeding months are the busiest of the year in this respect. Many plants that are not usually classified are given a look round now, and there are several important sections also needing attention. The Mexican *Lælias*, for instance, and especially *L. anceps* and *L. autumnalis*, will be starting, and in order to give them the full benefit of the new material the plant should be repotted in time to catch the first flush of young roots.

These, as a general rule, do not need a large amount of compost, and often a few bits of fresh peat and moss may be introduced about the young leads without really disturbing the older roots much, an advantage of course. But it should never be done when repotting is necessary, that is, when it is evident that the old material is in a bad state. Spreading laterally as these plants do, the extra size of the receptacle will need to be in width rather than depth.

Most of the *Cypripediums* again, as they go out of flower, will need attention, but here a different plan is necessary. The roots, though large, are not so easily injured; moreover, they take a new hold quicker than the true epiphytal roots of the *Lælias*, so in giving new material these should be well spread out and the compost worked between them. Only in the case of small plants and certain weakly growers is it necessary to keep the crown above the rim of the pot, the majority being better suited when kept about an inch below, as in ordinary potting.

Thunias, *Calanthes*, and the later flowering *Pleiones* also need attention, and in each case the procedure is very similar, all the plants delighting in a fair proportion of loam in the compost; and all must be done before young roots begin to push from the new leads. Large root-bound plants of *Cymbidium Lowianum*, *C. giganteum*, and a few others of this strong growing section, are rather difficult to deal with. Obviously it is impossible to separate the thick mass of roots, as tightly twisted as those of a pot-bound Palm, while in order to give a sufficiency of new compost a pot at least 3 inches larger has to be used.

This, when already the pots are large, soon makes the plants unwieldy, and as there comes a time when further increase of size is undesirable, it becomes a question either of feeding liberally and watering very freely or breaking up the large specimens into several. There is a decided advantage in favour of the latter course, as the roots once liberated, the dead roots in the centre, and the scoured or worn-out soil, can be removed.

Not many *Cattleyas* have as yet been repotted, but the time is not far distant when a number must be taken in hand. In every case remove as much as possible of the old material, replace it with new, and if practicable bring the lead from the rim towards the centre when replacing in the new pots. Sometimes the removal of a few worthless, worn-out pseudo-bulbs will make room for this without greatly increasing the size of the pot.

Among *Dendrobiums*, too, the grower will be increasingly busy, and here again it is not advisable to greatly increase the rooting space. With the deciduous and long-stemmed species generally there is little increase in size yearly, and therefore if the compost is kept sweet and open the plants may remain in the same pot or basket for years. The time to repot is when the young growth is an inch or so long, and before it begins to root independently. These are a few of the principal Orchids now needing attention, but of course there are many others.—H. R. R.

THE RENOVATION OF OLD FRUIT TREES.

IF we were asked to describe the age in which we live, I suppose we could not reply more aptly than by terming it an age of progress, marked by a steady, persistent onward movement from imperfection towards perfection. In all parts of the industrial world this progressive advance may be readily noticed. We can trace the formation of newer and better things to replace the old, and the equally important contemporary process of the remoulding of old things to serve the purposes of modern times. For it must never be forgotten that in all branches of industrial economy, it is a judicious combination of old and new which is best able to meet the demands that are made upon it. In our own particular sphere in the vegetable kingdom, this generalisation is well borne out, and I am about to endeavour to deal with one phase of the alteration of the old to keep pace with the new.

The word renovate or to renew carries with it the idea of rejuvenating, of making young, and consequently healthy and vigorous, that which has apparently arrived at an age not generally associated either with health or vigour. We have probably all heard of the wonderful mill which was accredited with the power of grinding aged persons into young ones again, and probably, too, none of us was very far in years before we relegated the story of the Mill of Life to the category of fairy tales. Well, I do not intend to discuss the impossibility of making old fruit trees into young ones any more than I should think of arguing in support of the mythical "Mill of Life," but I hope to be able to show, that in the case of fruit trees at least, old age is not so incompatible with health and vigour as may be generally supposed. The title of this paper, therefore, will not sound strange or unfamiliar to the thoughtful gardener who may be spending much time in improving old things, not, I trust, without a fair amount of success.

The subject of fruit culture to the present up-to-date gardener and farmer savours sufficiently of pounds, shillings, and pence to recommend itself, and with them finds practical exposition either in the planting of young trees or in bringing back to a healthy fruit-bearing condition those which have been planted half a century or more. But it is sad to see in so many gardens and orchards large numbers of old trees that have enough vitality left in them to supply, if properly treated, fruit which would be highly valued and appreciated on any gentleman's table and that would fetch a good price in the market, lingering out a practically useless existence for the lack of proper treatment. There are few farms but have their orchards of Apple and Pear trees; but it is, I am sorry to say, the exception rather than the rule to find the old trees in a healthy fruiting condition. This should not be so, for not only is it quite possible to renew in these old trees their former fruit-bearing qualities, but the means by which this desirable result is to be attained are available to all. From a commercial point of view the neglect of old trees is false economy, for I maintain that no portion of a farm or garden gives such good returns as a well-cared for Apple and Pear plantation.

The question has often been asked, "Why do not farmers take up fruit growing to a greater extent than is at present the case?" This question has a twofold answer according to existing circumstances. In the first place, there are some farms without orchards, and many farmers hesitate to venture on an undertaking from which little return may be expected for ten or fifteen years, although much labour and attention have to be expended during the whole of that time. Under the conditions on which so many tenant farmers now hold their lands, it is scarcely to be expected that they would care to embark on such a lengthy enterprise; the matter is a question for the landlord rather than for the tenant.

In the second place there are, as I have already stated, many farms with orchards composed almost entirely of old trees in an apparently decaying condition. To perhaps the majority of people an improvement in the fruit-bearing properties of such trees would be considered an impossibility, and a purely passive attention only would be given them. For farmers, as a body, lack the requisite technical knowledge for managing fruit trees, and in too many cases they do not study even the elementary principles which underlie successful fruit culture.

From the foregoing it will have been gathered that the renovation of old fruit trees is not the impossible or difficult matter which many persons may consider it to be. The question which naturally arises is, "What is the process of renovation?" My own experience may form a partial and perhaps not altogether uninteresting answer.

It fell to my lot some twenty-five years ago to take charge of a garden which contained a number of old espalier trained trees of the type that our grandfathers were so fond of planting all round the walks of the kitchen gardens. These trees had no doubt borne when young a small quantity of useful fruit, but in the course of time from hard pruning and the most unnatural style of training had become subject to canker and disease, and consequently useless. What was to be done with them? They were neither useful nor ornamental. I did not want to dig them up, as they were old favourites planted by some member of my employer's family half a century before, and to head them down promised to prove a dangerous undertaking. However, I obtained

permission to operate on one as an experiment. The tree I purposed to head down was an old Ribston Pippin eaten up with canker, and what small quantity of fruit it bore was as diseased as the tree itself. All the side branches of this tree were sawn off close to the stem at about the end of February. By the middle of April I noticed a number of buds forming all up the old stem. Eventually the tree broke splendidly and made some healthy growths of from 2 to 3 feet long.

In the following winter these were thinned, the strongest only being retained, and these cut back to a sound wood bud, pointing in an outward direction. The fact of this old stump showing such signs of new life made it an interesting study to my employer to watch its

FIG. 51.—LÆLIA EDISSA.

progress, because to him it was a great surprise that such a development should have taken place in an old tree. In the second year the growths were quite as strong as in the first, and during this time the lower buds of the first year's growth were developing into fruit buds. In the third year we had some splendid fruit—clean, and of the finest quality, without a sign of canker or disease. From that time to the present the tree has never failed to bring a crop of fruit, and last season I gathered from it 9 bushels of Apples.

I need hardly say that after this experiment I had a free hand in dealing with old fruit trees. We have no old espaliers left now, but the garden is well stocked with healthy "youthful" bush trees of from fifty to 100 years old, and it is from these that we get some of our finest fruit. My experience has not been confined to the class of tree I have just described, as I have dealt similarly with standard Apple and Pear trees as well.

I have spoken of heading down old trees as part of the process of renovation. In doing this it is well to cut the forked branches as near as possible on the upper side of the fork. The cut should be made in a slanting direction, the edges be rounded off, and a thin coating of green paint brushed over the cut, so that rain may be carried off and decay prevented.

In the case of old trees of a variety not worth preserving—that is, bearing a class of fruit of an inferior quality to some more modern introductions—the better plan, if the old stems are healthy, would be

to cut down the old stock as previously advised, and regraft with some known good variety. A new tree will form much quicker than from a maiden tree.—(*Paper read before the Reading Gardeners' Association by Mr. T. NEVE, Sindlesham.*)

(To be continued.)

SEASONABLE HINTS ON FLORISTS' FLOWERS.

THE winter is now, we hope, past, and the variableness of the season is manifested by the conditions in which gardeners find themselves in different localities. In this south-east corner of England where in many years our roads have been completely blocked with snow, and our gardens hidden under its white mantle, we have had hardly any snow or frost though friends have written of their gardens being covered to a depth of from 6 to 10 inches. Our springs were dry, and we were wondering whether we were ever to have a full supply of water again. Now floods have supervened, the ditches are full to overflowing, and the cry is heard, "When shall we have dry weather again?" Of course this affects our gardens, and considerably puzzles those who are engaged in cultivating florists' flowers.

AURICULAS.

I am in a somewhat peculiar predicament as regards these flowers. I have given away many of my plants, and my collection is consequently much reduced. I cannot look after them as I used to do, and just at the present time a spring has burst in my pit, and there is about 6 inches of water, but as this has happened before without causing any particular damage I regard it philosophically. It is not much that the Auriculas require at this season of the year, for the old practice of top-dressing them has been wisely abandoned, as experience proved that the formation of the truss had been completed before this, and stimulation could be better applied in the form of liquid. One has only to stir the surface of the soil, remove all dead foliage, and give the pits and frames a slight fumigation.

One cannot touch upon the subject of Auriculas without lamenting the falling off in their culture. Our largest grower for sale in the south said to me the other day, "There are no Auriculas to be had anywhere," and although this may be perhaps a little beyond the mark, yet there is no doubt that the stock of them in the country is being gradually reduced. To one like myself this seems a sad condition of things; we get hardly any novelties, and when three or four of our present growers pass away it does not seem as if there were anyone to take their places.

CARNATIONS AND PICOTEEES.

The season has, I think, been a favourable one for these where they are wintered in pots, but it must have been trying for those planted in beds. Where an even temperature is maintained and the plants are kept free from damp they winter well. My own culture of these is confined mainly to the varieties raised by Mr. Martin R. Smith and Mr. Douglas, and they are now so widely raised from seed that there is far less trouble taken with them than there used to be. How anxiously one used to watch over the named varieties and guard them from the vicissitudes of temperature through which they had to pass. Here, again, there is little to be done but to keep the plants clean and the surface of the soil stirred, and where they are bloomed in pots everything now ought to be made ready for potting. The soil should consist of turfy loam, well-decayed manure, leaf mould and sand, mixed and placed under shelter, so that it can be used at any time.

GLADIOLI.

It will be well, if any favourable opportunity occur and the ground is in good condition, to fork the beds over and prepare them for planting towards the middle or end of the month. Here again the practice of growing named collections has been largely abandoned and seedlings are substituted for them. The most careful growers now fertilise their plants, and the forms obtained from hybridised seed are very different from those that used to be put on the market where no care had been taken in crossing, as these produced very inferior flowers.

RANUNCULUS.

The sodden state of the ground effectually prevents the planting of these tubers, but it is much better to wait than to plant under present conditions. How people would open their eyes if one of George Lightbody's catalogues of Ranunculus, where some are priced as high as 21s., were placed before them, and yet one's earliest association of that which was most beautiful in our garden is connected with the old Dutch varieties of this beautiful flower. There is no product of the garden in which greater variety of colour is to be seen, while the exquisitely modelled forms are sure to attract every lover of the beautiful.

ROSES.

As far as I can judge our Rose plants have come through the winter grandly; there have been no frosts sufficiently hard to injure them, and the shoots are strong and healthy. The pruning knife will now be called into requisition; Hybrid Perpetuals may be pruned early in March, and Teas and Hybrid Teas a little later. So much has been written on the subject of pruning, and so complete and accurate a treatise has been put forth by the National Rose Society, that no grower of Roses who wishes to prune his plants properly can plead ignorance as to what he should do. There is one golden rule which ought ever to be borne in mind: where you have to prune a weak variety use the knife freely, cutting down to two or three eyes, while in the case of the stronger growing varieties five or six may be left.—D., Deal.

LOTHIAN STOCKS.

No Stocks are more valuable for winter, spring, and summer decoration than are these. Sowing the seed in July and August has been frequently recommended, but I find, after many trials, that those periods are too late for producing the best display of which these sweet and massive flowers are capable.

It may be well to explain what I mean by the "best display"—I mean large plants of double white, purple, and scarlet Stocks in the depth of winter. It is easy to obtain Stocks in spring and summer, and even at those seasons they are beautiful when the plants are well grown; but they are far more attractive from November until April, and withal they are easily produced at that period. When the sowing of Lothian Stocks is deferred until July or August the plants do not flower until late in the following spring, continuing through the summer precisely when other Stocks are plentiful. The true Lothian Stock, it should be remembered, requires a longer period of growth before flowering than does the ordinary type of the Intermediate Stock; the Lothian also lasts considerably longer after it commences flowering than the Intermediate—indeed, longer than does any other Stock in cultivation.

Seed sown in February or early in March produces plants which, if well managed, commence flowering about July, and continue until destroyed by frost. Such plants make most effective beds in the flower garden—beds as decided in their beauty and lasting as long as any other "bedding plants." As thus managed Lothian Stocks are very valuable. July and August sowings, as has been mentioned, produce plants which flower in spring, lasting also a considerable time; but the time of sowing for producing the best display I have found to be April, say, for the purpose of fixing it on the memory, on All Fool's day. By sowing at that time I have had plants in 8-inch pots—plants 18 inches high and about as much in diameter, perfect masses of double white and scarlet flowers (the purple is not so effective during winter) at Christmas and onwards until April. It is not necessary to dwell on the value of such plants for affording an abundant supply of cut flowers of the first order of merit, neither is a laboured eulogium necessary as to the commanding effect of the plants in the conservatory. At their period of flowering few plants can equal them.

My plan of raising the plants is to form a bed of leaves and litter about 2 feet high, nail four boards together to form a rude frame, and cover the bed with frame lights. Four or 5 inches of soil is placed on the bed, and in this the seed is sown thinly, very thinly, in drills. The plants are thinned to an inch or more apart as soon as they can be handled, and the glass is removed entirely during favourable weather. About the middle or towards the end of May the plants are very sturdy, and are placed into small pots just vacated by bedding plants. In these small pots the plants remain until they show flowers, when the spike of each double flower is cut off. Side shoots speedily grow, and as soon as these are seen the plants are potted firmly in rich soil in their flowering pots. These are placed on a hard bottom so that the roots cannot penetrate into the ground to any great extent, and a little litter is placed between the pots to aid in keeping the roots cool and moist.

The plants are subsequently treated as to watering the same as are Chrysanthemums, giving them liquid manure occasionally. They commence flowering in October, and an inch of the surface soil is removed from the pots and replaced with a rich top-dressing, after the manner of surface-dressing fruit trees in pots. The plants are then placed under glass in a minimum temperature of 45° to 40°. They flower splendidly all the winter.

This is the best way that I know of producing a fine display of Lothian Stocks. The plan is applicable to most gardens, and when plants are well grown they are worthy of a place in the choicest collection of conservatory plants during the winter months.—W. J.

Recent Weather in London.—The weather has, in the main, during the past few days, been dry and dull, with cold winds and occasional glimpses of welcome sunshine. On Sunday and Monday snow threatened more than once, but scarcely any fell. On Tuesday morning a cold drizzle fell for a short time. On Wednesday morning it was clear and very cold.

Weather in the North.—February closed with cold easterly winds, but a gradual tendency to drier weather. The first few days of March were fine, with a good deal of brilliant sunshine. On the morning of the 2nd 8° of frost, and on that of the 4th 5° were recorded, and there was again a sharp touch on Monday, the day being duller but pleasant.—B. D., *S. Perthshire*.

Apple Hollandbury.—I note the reply to a correspondent regarding this Apple. We have one tree of it planted with many more for trial purposes. It has fruited freely enough the last ten years, but the colour has never been what it ought to be. In every other respect, even to the habit of growth, this tree corresponds with what is said of the variety. The want of colour in the fruit appears the more inexplicable when I know that all other varieties colour profusely when growing in the same soil.—E. MOLYNEUX.

Isle of Wight.—The monthly meeting of the Isle of Wight Horticultural Improvement Association was held at Newport on Saturday last. The chair was taken by Mr. J. L. Mitchell. Mr. S. Heaton gave a practical demonstration in the "Pruning of Fruit Trees," showing how it should be done, and how it should not be done. The objects of pruning, the methods of pruning, and the seasons of pruning were dealt with at length, with the result that the subsequent discussion proved most interesting and profitable. A capital meeting was brought to a close by the election of several new members, and votes of thanks to the lecturer and chairman.

Chinese Primulas from Wem.—The name of Mr. Henry Eckford of Wem, in Shropshire, has become so intimately connected with Sweet Peas, that many people have taken the impression that to these plants alone the veteran horticulturist devotes his energies. This, however, is by no means the case, as the several excellent culinary Peas that have come from Wem go far to prove. But we must go much farther than this if we would enumerate all the plants that have been subjected to his attention. This cannot now be done, and we must be content with calling attention to the strain of Chinese Primulas, of which Mr. Eckford has favoured us with some examples. These have size, substance, and are beautifully fimbriated, while the colours are sufficiently distinct and attractive to insure general admiration.

London Open Spaces.—At a recent meeting of the Metropolitan Public Gardens Association, the draft final report of the Hampstead Heath (Golder's Hill) Extension Committee was submitted, and it was stated that with the conveyance of the estate to the London County Council at the end of last year the work of the Committee had been successfully completed, and that the small balance in hand would be devoted to a fund for the purchase of another addition to the Heath. The London County Council General Powers Bill was considered, and it was decided to oppose that part of it which proposed to give power to the Battersea Vestry to appropriate the Latchmere Garden allotment land, 11 acres in extent, to turn out the allotment holders, and to utilise the greater part of the site for building purposes. A letter was read from the Board of Agriculture enclosing a copy of the scheme for the preservation and management of Petersham Common, which embodied some of the suggestions made by the Association. It was reported that Christ Church (Blackfriars Road) churchyard had at length been transferred to the St. Saviour's Board of Works, and that the Association had commenced laying it out. An intimation was received from the Camberwell Vestry accepting the offer of the Association to lay out a recreation ground in Sumner Road, and it was agreed to put the work in hand as soon as possible.

The Royal Gardeners' Orphan Fund. At a meeting of the Committee of this Fund, held on the 2nd inst., Mr. H. B. May, Dyson's Lane Nursery, Upper Edmonton, was unanimously elected Chairman in succession to Mr. Wm. Marshall.

Royal Horticultural Society.—The next fruit and flower show of the Royal Horticultural Society will be held on Tuesday, March 13th, in the Drill Hall, James Street, Westminster, 1 to 4 P.M. A lecture on "The Evolution of Plants, illustrated by various garden strains coming true from seed," will be given at three o'clock by Mr. R. Irwin Lynch.

Anthurium Scherzerianum Saersii.—On the occasion of a visit recently paid to the gardens of the Chief Secretary for Ireland, over which Mr. G. Sayers presides, he showed me a form of *Anthurium Scherzerianum* named *Saersii*, which is practically a continuous flowerer for at least four months each year. The plant was carrying eight spathes; the length of the largest was 7 inches, and the width 3½ inches.—A. O'NEILL.

Certificates for Chrysanthemums.—At a recent meeting of the Floral Committee of the National Chrysanthemum Society it was decided to adopt a new method in granting certificates. In future novelties submitted will be judged by points, and in the case of cut blooms 18 points will be the maximum. The properties are divided as follows:—Breadth, depth, form, solidity, colour and finish, each of which may receive a maximum of 3 points. There will be three kinds of awards—viz., 1, first-class certificates for varieties that obtain 15 points or more; 2, awards of merit for those that gain 12 to 15 points; and 3, commendations for such as may get 9 to 12 points.

Measurements of Leeks.—The great interest manifested in the growing and showing of Leeks in the North of England is scarcely comprehended in the South where no special pains are taken in producing them in the great majority of gardens. If Leeks were not made a subject of study and earnest cultural effort in most northern gardens, a table of cubic measurements of examples of various sizes would scarcely have been required. Such a table, however, is provided by Mr. John Wear, Felton Mills, Northumberland. On a card a little more than 6 inches square, may be seen at a glance the cubic contents of more than 500 different sized Leeks. The contents of the smallest example in the table (6 inches long by 3 in circumference) is shown as 4.30 cubic inches and the largest (12 inches long by 8 in circumference) given as 61.12 cubic inches. Mr. Wear has certainly been very diligent, and his ready reckoner will doubtless be in demand in Leek growing districts, where a large number of cultivators exhibit the products of their skill at special shows of their favourite vegetable, though we do not know that there are classes for what may be termed the smaller fry in the table before us.

Winter Greens.—Nearly all descriptions of Winter Greens are rapidly becoming scarce. What with the great check given to summer growth by the drought of last season, the excessive attacks of aphids, which followed, and later the effects of severe frosts, stocks were far from plentiful, even before Christmas, and hard cutting of what was alive since has greatly thinned the crops. The best and cleanest of greenstuffs in the market just now, of home grown kinds, is Chou de Milan, or the strong-growing Hundredheads, which is one of the hardiest and most valuable of all the late white Kales. There is a fair supply of what are probably Cornish white Broccolis, very solid and tender, but these are of course expensive, costing 3d. and 4d. per head. Where there were good stocks of Ellam's and similar early Cabbages put out in September there should, provided they have escaped harm, be good material for cutting shortly. But where there are none it seems very likely that there must soon be a great scarcity of greenstuffs. It seems early to write about catch crops, as these are usually advised to be sown or otherwise prepared in the autumn. But none too early is it on warm borders to sow Spinach, Early Milan Turnip, Early Gem Carrot in a frame, and to get if possible strong Cabbage plants to put out close together for early cutting as Greens. Well favoured are the gardeners who have raised from seeds sown several weeks since plenty of strong young plants of Snowball Cauliflower, and in a frame dibbled out in October, or from a September sowing, plenty of good stout Cabbage plants. Some early sown Chelsea Gem Peas on a warm border also will come in helpful at a critical time, when other things are running short. No vegetable more greatly assists the gardener than does Seakale when roots for blanching are abundant.—OBSERVER.

The Royal Meteorological Society.—As this Society will attain its jubilee on Tuesday, April 3rd, having been founded on April 3rd, 1850, it is proposed to observe this fiftieth anniversary in a special manner. The Council have arranged for a commemoration meeting to be held at 3 P.M. at the Institution of Civil Engineers, at which the President will deliver an address, and delegates from other societies will be received. In the evening a conversazione will be held at the Royal Institute of Painters in Water Colours. On the following day, April 4th, the Fellows will visit the Royal Observatory, Greenwich, and in the evening will dine together at the Westminster Palace Hotel. In view of this jubilee celebration, Mr. G. J. Symons, F.R.S., was elected President at the annual meeting of the Society on January 17th, but owing to illness he has since been obliged to resign this office. Under these circumstances the Council at their last meeting appointed Dr. C. Theodore Williams as the President of the Society.

Liverpool National Amateur Gardeners' Association.—The oldest inhabitant of our city cannot remember such intense excitement as prevailed when the relief of Ladysmith became known. At the Common Hall, Hackins Hey, from multitudes of excited people the amateurs of both sexes had mustered in fairly good numbers. The paucity of exhibits was not to be wondered at, considering the spell of bad weather through which we have passed. After the newly elected Secretary, Mr. McGregor, had got his work well in hand and the Judges had completed their labours, the newly elected President, Mr. A. W. Ardran, gave one of his timely addresses. Speaking of the value of their Association as a means of mutual improvement, he remarked that gardening possessed claims such as nothing else could, and it was a remarkable fact that any particular hobby in it was oftentimes handed down in families for generations. Many failures amongst amateurs simply arose through not seeking information through the gardening press, or from an association such as theirs. The medals for points were distributed, Mrs. McGregor gaining the silver and Mr. Cangle the bronze, whilst Mr. H. A. Robins gained the certificate. The usual votes closed a most interesting meeting.—R. P. R.

Chester Paxton Society.—A meeting of this Society was held at the Grosvenor Museum on Saturday, when by special request the Honorary Secretary, Mr. G. P. Miln, delivered a lecture on the "Artificial Cross-Fertilisation of Cereals and Grasses." Although one of the objects of this Society when first started was to encourage agricultural as well as horticultural research, this is the first lecture on a purely agricultural subject that has yet been delivered to the members. Mr. Miln prefaced his remarks by giving some interesting particulars of the improvements that have taken place in the breeds of horses, cattle, and sheep during the present century, and which have led to such beneficial results to British agriculture. It was not, however, until quite recently that actual new breeds of farm plants had been produced by means of artificial cross-fertilisation. The lecturer explained in detail the methods adopted in securing improved breeds by the means of artificial cross-fertilisation, and stated that to the agriculturist "plant breeding" was almost as of great importance as was the judicious stock-breeding of horses, cattle and sheep. The lecture was copiously illustrated by a series of specially prepared lantern slides, which embraced all the reproductive organs of plants as well as comparative results between some of the old and the new breeds of cereals and grasses. Added interest was given to the meeting by an excellent collection of some two dozen varieties of Apples staged by Mr. N. F. Barnes, Eaton Gardens. Votes of thanks to Mr. Miln for his lecture and to Mr. Barnes for his exhibit brought the meeting to a close.

February Weather at Dowlais.—Total fall, rain and snow, 9.54 inches; deepest snowfall, 14 inches on the 13th, and 9 inches on the 10th and 14th. Snow fell on eight days to a total depth of 36.10 inches. Rain fell on twelve days. Heaviest fall 2.35 inches. The fall registered in five days from the 13th was 6.19 inches. Temperatures—Mean maximum, 37.857°; highest reading, 49° on the 25th, and below 32° on seven days. Mean minimum, 26.321°; lowest reading, 12° on the 6th and 12th. Below freezing point twenty-one nights. Mean in sun, 50.285°; highest reading, 75° on the 7th. Sunless days ten. The prevailing direction of the wind was N.E. and E. A very rough month throughout, especially on the night of the 13th, when a terrible blizzard commenced about 5 P.M., and was raging until 5 A.M. the following morning, the drifts of snow in some places being several feet.—WM. MABBOTT.

Sussex Weather.—The total rainfall at Abbot's Leigh, Hayward's Heath, the past month was 5.59 inches, being 3.60 inches above the average. The heaviest fall was 1.48 inch on 15th. Rain or snow fell on twenty days. The maximum temperature was 57° on the 24th and 26th; the minimum 16° on the 10th. Mean maximum 43.18°; mean minimum 32.22°; mean temperature 37.70, the average. A thorough "February fill dyke," as they say in Yorkshire. March has come in very cold but dryer.—R. I.

February Weather at Hodsock Priory, Worksop.—Mean temperature of the month 36.2°. Maximum in the screen, 58.0° on the 23rd; minimum in the screen, 13.4° on the 13th; minimum on the grass, 6.3° on the 8th. Number of frosts in the shade 17, on the grass 22. Sunshine 60 hours, or 22 per cent. of the possible duration. Rainfall 3.94 ins.; difference from average + 2.28. Rain fell on eighteen days; maximum fall, 0.97 in. on the 15th. Rain from January 1st 6.87 ins.; difference from average + 3.41. The wettest February for at least twenty-five years, probably for forty-five years. Sharp frosts in the first half of the month and deep snow.—J. MALLENDER.

February Weather at Belvoir Castle, Grantham.—The wind was in a southerly direction fifteen days. The total rainfall was 4.04 inches; this fell on twenty-one days, and is 2.23 inches above the average for the month; the greatest daily fall was 0.52 inch (snow) on the 15th. Barometer (corrected and reduced): highest reading 30.066 inches on the 8th at 9 A.M.; lowest 28.460 inches on the 19th at 9 A.M. Thermometers: highest in the shade 56° on the 23rd, lowest 10° on the 8th. Mean of daily maxima 41.14°, mean of daily minima 30.14°; mean temperature of the month 35.64, lowest on the grass 8° on the 8th, 12th, and 13th, highest in the sun 97° on the 18th and 23rd; mean temperature of the earth at 3 feet 37.60°. Total sunshine sixty-seven hours forty-five minutes, which is sixteen hours below the average for the month; there were nine sunless days. The rainfall is the largest in February since 1876, previous to which the records are imperfect.—W. H. DIVERS.

A Wet February.—The old saying "February fill dyke" must have originated in some such year as this. As a rule the month is one of the driest of the whole year, and in the South of England it is exceeded in this respect only by its successor, March. Every now and then, however, it is distinguished, says a contemporary, as in the present year, by heavy snows, followed by drenching rains, a very fruitful source of floods, as many previous records show. Last month was certainly one of the wettest Februaries we have ever had. Over a very considerable part of England the amount of rain and snow combined was at least half as much again as the average, and in many places it was at least twice as much as the normal. In London (at Brixton), where the total rainfall amounted to as much as 3.8 inches, the aggregate was nearly two and a half times as much as the average, and was the largest recorded in February since the year 1879. At Greenwich, where the total for the month amounted to all but 3½ inches, a long record extending back for sixty years gives only two instances of so wet a February, one of these occurring in 1879, when the total was 3.8 inches, and the other in 1866, when it was just over 4 inches.

Meteorological Observations at Chiswick.—Taken in the Royal Horticultural Society's Gardens—height above sea level 24 feet.

A dull, sunless week, with cold northerly winds and showers, at intervals.

STOPPING VINES.

"A. J." (page 182) in my opinion commits an error in not pruning his young Vines nearer the base than 18 inches. If he would prune them to within two eyes of the base, allowing both shoots to grow for a time, until he can be certain that the basal growth is free from slug or other insect attacks, and then remove the second shoot, he would find at the end of the season's growth a stronger cane. Under this treatment there is no need to retain a second growth for encouragement to the leader, as is his practice. In the future he would find the cane stronger near the base than is the case where pruned to within 18 inches of the soil. It is the stout basal growth that should be encouraged the first year as a foundation for future greatness. If "A. J.'s" intention is to establish Vines to give annual heavy crops of fruit for say twenty-five years, I should advise him to cut the leader harder back than to within 4 feet as advised. My experience is, Keep the rods well back the first two or three years until they gain strength. I have seen many young Vines left with 6 feet of leader with a view to cover their allotted roof space in a short time. Such Vines nearly always exhibit weak places in the rods, and if they do not swell regularly, no after treatment will bring about that equality of rod thickness which is so desirable, not only for appearance, but for a full crop of high-class Grapes.—E. MOLYNEUX.

PRIMULA KEWENSIS.

No doubt it is somewhat imprudent, if not impertinent, to suggest that anything emanating from the Royal Gardens, Kew, merits adverse criticism. But I was not alone at the Drill Hall on the 27th ult. in thinking that the giving of so specific a name for a large flowered variety of *Primula floribunda*, as the above designation is, was rather premature. When Kew says that the plant was the product of crossing *P. floribunda* with *P. verticillata*, of course no one should dispute it. But still, even the most willing believer likes to see some tangible evidence of the cross in the result. In this case the plant was simply a *P. floribunda* in every respect and no more, not the least evidence of the potency of the *verticillata* parentage being visible. Naturally it looked fine when compared with a poor specimen of *floribunda*. I should have thought, coming as the plant did from our great Botanic Garden, that it would have been so much better to have called it *Primula floribunda grandiflora*, which it is, than by the specific name of *kewensis*. What if it seeds, and in that way reproduces *floribunda* after all? Where will the new appellation come in then? Oddly enough no family of plants seems to have been less responsive to the efforts of hybridists than has that of the *Primula*. Even the assumed crosses of *P. obconica* and of *P. sinensis* leave ample room for doubt. Ordinary growers of the former species find with constant selection that considerable variation in flowers and leaves result, but there are in such cases no suspicions of intercrossing.—SCRUTATOR.

SPRING SPRAYING.

HAVING been asked by several gardeners if I had done my spring spraying yet, I think it may interest others to learn the results of that done last March, when I used nearly 1000 gallons of mixture on 2000 fruit trees. These we have just finished pruning, and they look very well. The boughs are a beautiful deep healthy green, clothed with plump fruit buds, promising a fine crop. The moss and lichen have quite gone. The mixture used for spraying was caustic soda 5 lbs. (Greenbank's 98 per cent.), pearlash 5 lbs. Dissolve the caustic soda carefully in boiling water. Pearlash will dissolve in cold water, but I prefer hot, as it is quieter in its action. Add these together, and put them into 50 gallons of rain water. In small gardens this mixture can be applied with a syringe, but in large orchards a sprayer is best.

I claim another great merit for this mixture—viz., it destroys the codlin moth (*Carpocapsa pomonella*). My trees have suffered much from it in the past. Bushels of fruit have prematurely fallen, but last season the dreaded foe did us no harm. So convinced am I that this blessing resulted from my caustic spray, that I intend to give the trees another dressing with it this year about the middle of March. On 1st May, 1899, I tried a stronger solution than the above—viz., 2 lbs. caustic soda and 2 lbs. pearlash to 5 gallons of water, with the result that the trees looked very unhappy all the summer, and this winter I have taken their heads off. To use the mixture at this strength is wasteful and dangerous.

Another good mixture for spraying trees at any time when in growth is given by Mr. L. H. Bailey in his "Principles of Fruit Growing,"—viz., 1 lb. of Paris green to 200 gallons of water. This is a serviceable wash. To it may be usefully added 2 lbs. of lime. Or a pound of Paris green may be added to 200 gallons of Bordeaux mixture. If the Paris green be made into a paste with a little water it mixes better in the barrel. For the blue-head caterpillar, or figure 8 moth, I used with success 2 ozs. of softsoap, and one-third pint of nicotine in a gallon of water. This is cheap and effective.—JNO. MILES, Southampton.

FROZEN WATER PIPES.

I THINK that if I state the fact "That 9 cubic inches of water becomes when frozen 10 cubic inches of ice," readers who may not be already convinced by the arguments which have already been brought forward will be able to see that if a pipe is already full of water, it must break if it cannot expand, to make room for every 10 inches to replace the 9 inches. But if there should happen to be room in a pipe for the 10 to replace the 9, there would certainly be no danger when every 10 cubic inches was again replaced with the 9 cubic inches of water in the thawing.—J. L. W.

DECADENCE IN WALL TREES.

I AM afraid that one of the reasons of the bad training of the present day is not so much the want of knowledge as the lack of time; the garden staff, as a rule, is not strong enough for a man to devote sufficient time to the fruit trees. When the gardening account has to show a balance in hand there is often something which is not done, either when or how it should be. If fruit trees are to be trained straight and at correct distances, the young shoots must have attention in the summer as well as winter. As regards the unfruitfulness of wall trees which is apparent in large as well as small gardens, even after good training has been bestowed upon them, overcrowding of spurs and want of sufficient support are two of the principal causes. I speak from experience, as I have brought old unfruitful trees back to fruitfulness by thinning and feeding.—J. L. W.

BIRDS AND BUDS.

I SYMPATHISE heartily with Mr. Kneller in the trouble he has with wild birds, which is not his alone, as I have heard of others in certain districts where trees and birds abound, and they are as rigidly preserved under the influence of modern sentimentalism as are pheasants and hares. Therein do we see one of the strange inconsistencies of humanity, for whilst the very persons who refuse to allow a sparrow or a tomtit to be shot in a garden, where they are doing immense harm, will yet take part in a battue and glory in having shot their hundreds of half tame, harmless pheasants. Personally, I would not shoot a bird or animal of any description except to convert it into useful food, or even harm any insect except to protect myself from its depredations.

My inoffensive action, however, towards all things living must not prevent me from holding that when wild birds commit such depredations in gardens as they did at Malshanger, that they should be destroyed. Why tolerate birds to do such enormous harm to our fruit crops, when we destroy rats wholesale when they prey upon our corn stacks? Are not rats as worthy of some sentimental protection as devouring birds? The law, through the County Councils is showing itself to be on this matter a "hass," and is only giving these birds liberty to prey upon and devour our fruit crops. What nonsense is it to be crying after more home-grown fruit, and yet protect by the law some of the greatest enemies to fruit culture we have in birds.—A. D.

JUDGES AND JUDGING.

WHEN "An Inquisitor" (page 179) undertakes to call into question the practice of employing judges to act as such in connection with the same classes or departments at shows successively, he should realise that generally the practice has worked well, and that in indicting the practice it is his duty to set out his reasons for such objections. But in the present case he indicts the practice without presenting any reasons or grounds, and invites others to defend a practice that, so far as I can perceive from his article, needed no defending. What does he say to the practice in relation to Chrysanthemum shows, where the same men judge the same classes year after year with good results? Does he suggest that Orchid men or Rose men, or vegetable or fruit men, should be put on to such duties? The same thing applies to Roses, Dahlias, Carnations, to fruit or vegetables, or to any other special exhibition section in flower shows.

Judges are usually selected by exhibition committees because of known reputation in relation to certain sections of horticulture. One man is well up with plants, another with florists' flowers, another with table decorations, yet others with fruit and vegetables, and so on. No doubt most of these men could judge in other classes, but everyone familiar with shows knows how great is the risk attendant upon putting round men into square holes. When we see the same men engaged year after year by the same committees, certainly conclusive proof is afforded that such executives are entirely satisfied. It should not be assumed that such selection takes place in defiance of exhibitors' wishes, as committees are usually quick to act when they find exhibitors have good ground for complaint. I do not see that "An Inquisitor" has any cause to fear others' wrath, but at least he might have started the subject by giving his reasons.—A. KINGSTON.

SOME OF THE BEST NEW ROSES.

I PROMISED on page 132 to enumerate a few of the newer Roses, and can conscientiously say that all of those named below are decided acquisitions to our already long list of superb varieties.

Ulster.—This is a grandly formed flower of great substance. I have seen it on several occasions, and flowered it last summer. It is a robust variety, free-flowering, after the form of Lady Mary Fitzwilliam, and sweet scented. Unfortunately its colour is scarcely so clear a salmon pink as one might desire, and it is more subject to mildew than most. It won a gold medal of the N.R.S. in 1898.

Mrs. Edward Mawley.—There can be no two opinions as to the beauty of this new Rose, which also secured a gold medal from the N.R.S. For form and size it is perfect, and the plant is very free-flowering. In the N.R.S. catalogue it is given as high-centred and imbricated; pink, tinted with carmine, and moderately vigorous.

White Maman Cochet.—All Rose growers know Maman Cochet, and I need only say that this sport from it is a counterpart in every way except in being white with a slight tinge of lemon.

Bessie Brown.—This will take rank as one of the very best Hybrid Teas. It is a creamy white, quite distinct, and when I first saw it at the Crystal Palace some four years or so back, I noted it as the best in a box of new Roses, and find it on my notes as "an improved Lady M. Fitzwilliam, but lighter." It is quite a distinct grower, and of perfect form. Not only did this Rose secure a gold medal as a new variety, but one of the silver medals as the best bloom among Hybrid Teas in the exhibition of the N.R.S. held at Bath in 1898.

Sunrise.—This variety gives us one of the prettiest of garden decorative Roses, and it has a most exquisite scent. It is doubtful if there is a freer grower and bloomer. For forcing it is most useful, and it is sure to be in much request. The colour is a peculiar reddish carmine shaded with salmon and fawn yellow. It is very pretty in the bud, and with deep bronzy foliage. This was the only gold medal Rose of last year.

Mrs. Cocker.—I believe this is a seedling from Madame Gabrielle Luizet and Baroness Rothschild. It is a beautiful soft pink, very high centred, grand in petal, and full. One of the most distinct and useful of all pink Roses.

Admiral Dewey.—This will be welcome as a pale pink sport from such a grand variety as Caroline Testout, which it resembles in all but colour.

Psyche.—We saw this at the Crystal Palace in 1899. It is a pale rosy pink, very small flowers, somewhat after a Crimson Rambler in growth, and likely to be a good companion to that variety.

Papa Lambert.—This has a very large flower, is sweetly scented, pinkish rose, with deeper centre, and is likely to prove one of our best Hybrid Teas for pot work.

Maid of Honour.—This is another of the good sports from Catherine Mermet, and may be briefly described as an improved Bridesmaid, its deep pink being very rich and glowing. This is sure to take a place in every collection, however small.

Madame Lucille Coulon.—This is a peculiarly coloured Rose, being rosy flesh with a distinct shade of copper and gold. A good grower, and very free blooming.

Billiard et Barre.—This is a golden yellow, charming in the bud stage, and filling out to a large flower.—PRACTICE.

BRUGMANSIAS.

HALF a century ago these were amongst the most popular plants of the greenhouse, but doubtless they have had to give way to modern, if not more attractive introductions. I have a vivid recollection of my first acquaintance with either *B. arborea* or *B. suaveolens* (the two varieties are considered as synonymous by some, but the distinction consists in the flowers of the former being less fragrant than those of *B. suaveolens*; moreover, in the former the flower has long tails attached to the corolla lobes, whilst in the latter there is hardly any prolongation of the segments) some fifty years ago in the shape of two fine old specimens of the varieties in question growing in the centre bed in a large conservatory at Sarsden House, near Chipping Norton, Oxon, then the seat of the late Mr. J. H. Langston, M.P. The specimens were the first my juvenile eyes had ever seen, and my father's respected old friend, the late Mr. John Greenshields, the gardener, took considerable pride in the veterans. Since then I have occasionally met with similar, and even finer specimens, growing in large tubs, boxes, and planted in the border, but not to the extent their merits

deserve. For certain decorative effects the cut flowers lend themselves admirably, and also keep fresh for several days in water if cut before they are quite expanded.

B. suaveolens is sometimes called the Angel's Trumpet Plant; the flowers are somewhat larger and longer than those of *arborea*, and measure sometimes over 12 inches in length, and the perfume is exceedingly strong. The flowers of *B. arborea* grow from 6 inches to 9 inches in length only, and the plant is naturally somewhat taller than that of *suaveolens*, though the distinction may be considered as hair-splitting, similar to the two generic names of the plant—viz., *Brugmansia* and *Datura*, and botanists aver there is no material difference between these species. *Brugmansias*, however, are all shrubby plants, and *Daturas* are nearly all annuals. Strictly, there are only three shrubby species—viz., *B. sanguinea* or *bicolor*, a native of Peru; *B. arborea*, also from Peru; and *B. suaveolens*, a native of Mexico principally, yet occasionally found further south. There are several supposed varieties, but these are made synonymous with the three species mentioned. The more commonly grown species in our gardens is *B. Knighti*, a double petalled kind. It possesses a sturdier habit, and is admirably adapted either for pots in the greenhouse, or sub-tropical bedding. There is also a variety of *B. sanguinea* called *flava*, the flowers being completely yellow, but it is somewhat rare.

In outward aspect the *Brugmansias* are not to be distinguished from the *Daturas* by the casual eye, as the flowers have much the same appearance. Formerly, indeed, no distinction was made between them, the name *Datura* covering all. Gradually a more rigid line was drawn by botanists, and they were differentiated into two entirely distinct genera. This separation was based upon the characteristics of the fruit and not upon those of the flower. The fruit in the *Brugmansia* is smooth, and has a tendency to subdivide into two cells, while the fruit of *Daturas* is spinous and subdivides into four cells. *Brugmansias*, moreover, have a shrubby habit. The properties of both, like those of the *Nicotianas* and the *Henbanes*, are acrid, and in many cases poisonous. The near relatives of the *Brugmansias* which, if not indigenous, have become acclimatised in these islands, are the Deadly Nightshade, the Thorn Apple, and the Black Henbane. All of these have a doubtful reputation and are not usually suspected of being allied to those other very popular members of the order *Solanaceæ*—to wit, the Potato, the Tobacco, and that ever-growing favourite, the Tomato. An interesting order surely is this of the *Solanaceæ*, which comprises so many plants of an ornamental, useful, and dangerous character.

For some reason the name *Brugmansia* has been given to certain parasitical plants allied to the giant *Rafflesias*, which stand far apart from the *Solanaceæ*, and cannot be regarded as having so high an organisation.—W. GARDINER.

TOMATOES.

SEEDS for producing the main crop of Tomatoes, either under glass or outdoors, ought now to be sown, so as to have plants strong and vigorous for the final potting or planting out. The seeds can be sown thinly in pots in any light sandy soil. If the seedlings are crowded they will be weakly from the commencement, which causes delay in pricking out the young plants. In a temperature of 60° to 65° seeds germinate quickly. Immediately this has taken place elevate the pot or pan containing them close to the light in the same temperature, thinning out the crowded seedlings. The next proceeding consists in transplanting them from the seed pots to others, placing them round the edge, three plants to a 3-inch pot, or if smaller pots are used one in the centre. Sink the seedlings so that the stems, hitherto exposed, are buried to the seed leaves. A light mixture of loam, leaf soil, and sand is the best compost. Use it in a moist condition, and stand the pots on a warm sunny shelf, affording no shading. Water sparingly in the first instance, but when growth is in active operation frequent attention will be necessary, especially in sunny weather.

On these plants becoming strong and the roots fairly numerous, move into 4½ or 5-inch pots. Drain the pots moderately and work the soil firmly about the roots. Stand them again on a shelf in a heated house to encourage rooting, but when fairly started remove to a similar position in a cool house with plenty of ventilation, as the plants must not be allowed to be drawn up weakly by even a day's neglect. Gentle heat, plenty of air and sunshine, adequate moisture at the root, and a moderately dry atmosphere are the indispensable conditions for insuring strong plants. Such will soon commence to produce flower trusses, and if they do flower and set a few fruits prior to the final potting or planting out, it will be an advantage rather than otherwise. They must not, however, receive a check by retaining them too long in the pots to enable them to flower. It is necessary to transfer them to their fruiting quarters before they become root-bound. When the roots mat themselves round the ball of soil in search of fresh food, the growth of stem and foliage proceeds, but it is of a very weak character, hence the importance of finally potting or planting in good time, when this difficulty is obviated.

The right condition of the plants for the final shift having been pointed out, a brief discussion on the best positions for planting under glass may be helpful to some. The best and most profitable crops are to be obtained from plants which can be set out on a stone

Tomatoes may be planted on mounds of soil in the centre border, where there will be room for a good length of stem to be trained to a perpendicular stake. Tomatoes on side stages should be attached to wires under the roof. The plants may be arranged a foot apart,

FIG. 52.—BRUGMANSIA (DATURA) ARBOREA (?).

stage or an improvised wooden bench not far from the glass and over some hot-water pipes. Not much depth of soil is required for giving the plants a start; just sufficient to cover and surround the ball of roots is ample, but it must be made firm. In a light, sunny house

training to a single stem. On the floor of the house give them more room. A space of 20 inches will be best, but regard must be had to having sufficient space for cultural operations, and when a large area is covered leave out a row between each three or four to admit of

passing among them for this purpose. The single stem method of training is the simplest and easiest, and produces good crops.

Where planting out is not practicable pot culture must be adopted, good results following this method; 11 or 12-inch pots provide the necessary root room, giving efficient drainage. The compost ought to be substantial and good, but not over-rich. Three parts of turfy loam to one of decayed manure, with wood ashes and sand, will form a suitable mixture. Previous to potting or planting out finally see that the soil in the pots is thoroughly moist, not wet. Turn out the plants, remove the crocks at the base, then fix the plants on a layer of soil about an inch thick. Surround the ball with more soil, making the whole firm, but add no more than will cover the whole. This will be sufficient until the first fruit has set and active roots begin to work through; then add some more, the fresh character of which will encourage the production of new fibres.

After fruit has set freely these frequent top-dressings will be of great assistance in supporting the crop. Further feeding should be carried out by the aid of liquid manure made from horse, cow and sheep manure, using a peck of manure to 25 gallons of water. Tie the manure in a bag, sinking it in the water in a tub. Give an application once or twice a week. Soot is an excellent fertiliser for Tomatoes. Tie a peck of fresh soot in a bag, which place in water in a tub holding 25 gallons. In a few days clarify the mixture by adding a spadeful of lime. This makes the liquid as clear as wine. Occasionally give Peruvian guano 1 oz. to a gallon of water, or nitrate of soda $\frac{1}{4}$ oz. to a gallon of water. The nitrate must only be used when a heavy crop is being carried by the plants, otherwise its effect would be injurious.

One important detail in the culture of Tomatoes ought not to be overlooked, and that is the rubbing out of side shoots from the axils of the leaves on the main stems. Also afford constant ventilation, and in dull weather use gentle fire heat. In sunny weather with a little breeze the flowers will disperse their own pollen, but it is usually advantageous to shake the trellis at midday so as to scatter it and insure some grains falling on the stigmas.

Blackwood Park Prolific, Duke of York, Perfection, Chemin Rouge, Frogmore Selected, Blenheim Orange, Golden Perfection and Golden Nugget are among the best varieties of Tomatoes. Sutton's Maincrop is good for the open air.—E. D. S.

HARDY BORDER FLOWERS.

ARABISES.

THE most useful of the Arabises for border cultivation are *A. albida*, *A. alpina*, and the variegated variety of *A. lucida*. Of these the best for floral effect is either *A. albida* or *A. alpina*. There is little to choose between the two, but the former has the larger flowers. Both are pure white, and in masses give a fine effect in spring, when their sheets of snowy flowers are at their best. They delight in light soil, and in such bloom more freely and the plants reach a larger size. The new double variety of *A. alpina* I have not yet flowered, but it is highly spoken of by some. It ought to last longer in flower than the single forms. *Arabis lucida* is often used for edgings or lines. Its variegation is effective, and at some seasons is much admired. The flowers themselves are not equal to those of *A. albida*. It may be mentioned that there is also a variegated form of *A. albida*. *Arabis lucida* likes a rather heavy soil and a cool climate. Several other Arabises are more suitable for the rock garden, and are thus omitted.

ARENARIAS.

There are not many of the Sand Cresses which are of much value for the border, their uses being more apparent in the alpine garden. *Arenaria graminifolia* is occasionally used, but it is not very effective in the border. It has white flowers on simple erect stems, and grows from 6 to 9 inches high. The best of the genus for our purpose is *A. grandiflora*, a really beautiful plant for the front of the border. It is dwarf and compact, only growing about 6 inches high, and has pretty white flowers which are large for the size of the plant. It will grow in almost any soil, and is increased by seeds or division.

ARISEMAS.

These Aroids are only to be recommended to those who can appreciate plants of uncommon appearance, that are more valued for their singularity than for bright colouring. They are thus not to be suggested as flowers for what is fitly called the "dressed border," as their charms consist in other qualities than those which appeal to the gardener of ordinary tastes. One of the best of the hardy species is *A. triphylla*, which grows about a foot high, and has green and purple brown spathes and brown spotted spadices. The leaves are trifoliate. Another hardy species is *A. ringens*, whose spathes are green, white, and purple, and whose spadix is of a yellowish green. This species is a native of Japan, the former one coming from North America. The *Arisemas* like a good soil, and are increased by division.

ARMERIAS.

The *Armerias*, or Thrifts, form a pretty group of plants, some being of considerable beauty. The dwarf species are sometimes used for edgings, but may also be grown in clumps further back. The taller species are pleasing when in bloom and a few are useful for cutting. One of the most pleasing is the tall *A. cephalotes*, the Round-headed Thrift or Sea Pink. It grows from about 12 to 20 inches high, and is a handsome and desirable plant. Unfortunately it is not a long-liver, and ought to be raised from seed every year to avoid the risk of losing it. It has several synonyms, but is generally known by the name here used. The next in value, so far as regards beauty, though it is superior as regards its perennial habit, is *A. plantaginea*. The flowers of *A. cephalotes* vary from white to bright rose and almost crimson, but those of *A. plantaginea* have neither the white nor the crimson shades. The common Sea Pink of our coasts is occasionally grown, together with its white variety. *Armeria maritima* is hardly bright enough for many purposes, and those who want a Thrift of the same size but deeper colour should procure the variety named *A. m. Lanchana*, with deep pink flowers. The Thrifts are not difficult to grow in ordinary soil, and may best be increased by seeds or division. Cuttings may be rooted in a frame or under a hand-light.—S. A.

GROWING GLOXINIAS.

WE admire some plants for their handsome foliage, others for the beauty and size of their flowers, and some for their graceful habit of growth; but when we find these three good properties combined in a great measure in the *Gloxinia*, we are not surprised that it is generally appreciated and cultivated. Its fine, rich, trumpet-like flowers, either of distinct colours, white, crimson, blue, purple, or pink, striped, mottled, edged, or blotched with carmine, blue, bright rose, and blush—either rising boldly above or resting on its fine, rich, velvety, large, and beautifully-veined foliage—give to the whole plant when properly managed a fine, massive, and graceful appearance, like a bouquet handsomely and artistically arranged.

Although *Gloxinias* generally receive the same treatment as other tropical plants, nevertheless, amateurs and others who have a warm greenhouse and a frame heated by manure can grow them to as great perfection as where they are allowed a higher temperature. Sow the seeds in pots of light sandy peat at once; fill the pots half full of crocks, over which place a layer of moss and peat, after which sift a little peat and sand very fine, distributing the seed evenly thereon. It requires no covering with soil. Water with a very fine rose, cover with a bell-glass, and plunge the pots in bottom heat. In ten days or a fortnight the plants will appear. Give air by degrees. When they have formed three or four leaves transplant them into 3-inch pots, and if properly supplied with heat and moisture the plants will bloom in the autumn of the same year. They should not be dried-off until the second year, as the small fibres are not sufficiently strong to cause them to start vigorously in spring. This remark is also applicable to young plants raised from cuttings.

The stock can be readily increased, as almost every part of the leaves will form plants if a portion of the midrib be retained in each cutting. Divide the leaves transversely, place them in pots of fine sand, cover with a bell-glass, and plunge in a strong heat; in a short time callosities will form at the base of the cuttings. Repot in good sandy peat, replunging and covering with a hand-glass, giving air occasionally. If the plants to be propagated are very choice, remove them into a large pot, making incisions on the midrib of the lower leaves, placing a few pebbles on the leaves to keep them to the soil; this is the safest method. They will soon root if a good heat is maintained, and may be repotted immediately.

February or the beginning of March is the best time for starting the old plants after their winter rest. In potting, the old soil should be carefully removed from the roots. In planting, press the roots gently on the surface of the soil, and give them no water for some time. The soil should consist of half peat, one-fourth loam, and one-fourth leaf mould mixed well together, and used in a moderately rough state. A thorough drainage of crocks is indispensably necessary. As they progress in growth and fill their pots with roots they are to be liberally shifted, not exactly on the one-shift system, but approximating to it—that is, from a 5-inch to an 8-inch, where they will attain a size, luxuriance of growth, and profusion of flowers suitable for exhibition or for adorning the conservatory. The soil should be gradually enriched with some well-decayed manure until they receive their last shift, when more loam with less peat and a liberal addition of decayed manure may be given, the soil being used in a rough state.

After they are all potted remove them to a frame where the temperature is about 60°, and when they have commenced growing give them a little water, increasing the quantity as they advance in growth. A little air must be given in fine weather. During their season of blooming a watering with weak liquid manure (sheep's, pigeons', fowls' manure or guano) may be given occasionally, which will increase the luxuriance of the foliage and the brilliancy of the flowers. When flowering is finished water must be gradually discontinued, and at last entirely dispensed with, when they should be removed to any out-of-the-way shelf in a warm greenhouse for two or three months until February, when the season for fresh growth again arrives.—J. H.

GEUM COCCINEUM FL.-PL.

THIS is one of the earliest, brightest, and finest of hardy border plants; it is late as well as early, for it flowers with me from early spring to late summer. I use immense numbers for decorative purposes, for which they are particularly valuable. Of course it is well known that the flowers (fig. 53) are of a brilliant scarlet colour. The plants are raised from seeds sown and treated precisely similar to Sweet Williams. A bed of this fine old semi-double Geum should be in every garden where a supply of scarlet flowers is required for vase decoration. Young plants have finer flowers and produce them more continuously than old stock, and hence it is advisable to sow a few seeds annually so as to insure a number of vigorous plants. Plants raised from seeds sown now would in all probability yield some flowers next year, and would certainly produce an abundant supply the year following. It is a border flower of the first order of merit, but to see it to the best advantage it should be grown in large masses.—F.

GLADIOLUS CULTURE.

THE Gladiolus has become a favourite flower, and many of its varieties are so reduced in price that it is now within the reach of all. It has many good properties, one of its greatest is its suitability for decorative purposes. When cut and intermixed with other flowers for the drawing-room it will not wither in two or three days, as an ordinary flower does; but with care and attention in taking off a little of the lower part of the stem, supplying fresh water, removing the decayed blooms, a succession of expanding buds enables it to retain its place for a fortnight at least.

It can be advantageously appropriated to window decoration, interspersed with other plants to form a contrast. Take a bottle, of which the neck must be sufficiently wide to admit the stem of a Gladiolus, and plunge it into soil in a flower pot—a deep narrow one is the most suitable for this purpose; fill the bottle nearly full of water, and cut the spike the height that may be required, introducing a few blades of its foliage to give it the appearance of a growing plant. By attention as above, of course preventing the rays of the hot sun from falling directly upon the spike, I think that all who try this method will feel themselves compensated for the slight trouble they have taken. Those who grow the bulbs in beds or groups can always take a few spikes for this purpose without materially injuring the appearance of the garden, hence one of the advantages of grouping.

A succession of bloom may be kept up by amateurs for from four to five months. There are two ways of accomplishing this. 1st, by planting at different times; 2nd, by a careful selection of large and small corms.

Perhaps I may here be permitted to say that I have been an ardent amateur for very many years, and have cultivated bulbous-rooted plants to a considerable extent. I commenced the culture of Gladioli as soon as they came into repute, and have paid special attention to them. They are hardier than the generality of people are disposed to think; however, I paid a penalty in testing their hardiness by losing upwards of 200 bulbs; but under ordinary circumstances and in a favourable situation they may with safety be planted, weather permitting, in the latter part of February or the early part of March. When they are about to break through the surface a little protection is necessary, such as straw, dry litter, or cocoa-nut fibre refuse.

CULTURE IN POTS.

Some persons recommend artificial heat, which I strongly object to for corms that are intended for the open ground; but if early blooming is required, I rather prefer to plant in pots and plunge in a cold frame, choosing my largest corms and the early varieties for this purpose; in fact, I consider it a good plan to plunge in this way at different periods, to obtain a succession of bloom when there is convenience at hand to do so.

In potting for the cold frame first insert crocks, then a little sound turf mixed with sand and leaf mould; next put in the corm, and cover it with sand and crushed charcoal, filling up with the previous compost. Be cautious not to give too much water. When planting out, remove the top soil, or rather turn it back, and add a little more sand and charcoal.

I would impress upon all cultivators of the Gladiolus the absolute necessity of a dry bottom or good drainage. I have been rather amused at the detailed account given me by a friend's mode of growing. He digs out his bed to a depth of 3 feet. The first layer consists of 4 inches of turf; then I calculate that there will be 9 or 10 inches of decayed cow manure (it is a pity to waste such good stuff, it often cannot be obtained), and 18 inches of turf and loam; then come the corms in cocoa-nut fibre, and 4 or 5 inches of turf and loam upon this, making the 36 inches. Had I to make up his bed, and 3 feet deep, my experience would lead me to proceed as follows: 6 inches of brick rubbish, then turn back upon this 8 inches of the top soil taken out,

with a little sand added, as it is strong; upon this 5 inches of the decayed cow manure, and 13 inches of the turf and sandy loam; then my corms smothered in a little clean river sand, mixed with bruised charcoal, completing with 4 inches more of the turf and sandy loam, of course thoroughly incorporated.

The following, which is my own mode of culture, I have invariably found successful:—Bed 30 inches in depth; bottom dry, of course. Turn back 10 inches of the top soil taken out, put in 4 inches of old cow manure, then well-mixed turf, sand, and loam, with the addition of a little old leaf mould, if certain of its containing neither fungus nor anything to create it, to the depth of 12 inches. I then plant my corms covered by a little clean river sand, mixed with crushed charcoal, and a covering of 4 inches of turf and loam. Protect as above. I do not object to silver sand, but it is in some cases more expensive, and I consider the other quite as advantageous.

GROWING IN BEDS.

I am not an advocate for growing Gladioli in beds unless the blooms are required for exhibition; when this is the case the corms should be planted 8 or 9 inches apart each way, leaving a groove between the

FIG. 53.—GEUM COCCINEUM FL. PL.

rows for the purpose of applying liquid manure if necessary, as I strongly object to any kind of manure coming in close contact with the corms. It is better, as a safeguard, to water the bed slightly before applying the liquid manure, and also again after doing so.

If not wanted for exhibition, I prefer grouping five or six corms together, or as number and convenience suggest, the soil being prepared in the same manner. In the autumn, when I take up my corms, I treat them in the same way as I usually do Tulips—simply drying, and protecting from frost during their time of rest. I throw out the soil upon a space prepared for it to the depth of the cow manure. I then have the latter forked up with a portion of the soil below it, turning this over frequently to temper it thoroughly, at the same time turning over what had been previously laid out. When planting time draws near I add a little more decayed cow manure, and then fill in the soil that has been thrown out. This I have done for some years and have never been disappointed with the result.

When leaf mould is introduced, let it be leaf mould, not decomposing leaves. Nothing to my mind is more injurious than decaying sticks or timber. Pieces of the former are invariably mingled with decaying leaves, and as invariably fungus is produced. Of all edgings for beds, avoid wooden ones; the boards and stays employed are almost certain, sooner or later, to produce fungus, a consequence of all others to be feared. I do not know of anything else which has such an injurious effect upon corms.—FLORA.

THE MAGIC OF SUNSHINE.

THE mists and fogs which rise from our watery surroundings have too long hung like a pall over the British Isles. Day by day, almost week by week, the gloom of a sunless sky has been relieved only by an occasional downpour of rain or a blinding snowstorm. If it be true that the restless energy and dogged determination of the Briton are caused by the climatic variation under which we are reared, surely in the future we ought to be more determined than ever, for a nation who can press steadily, hopefully, onward in spite of depressing news received during dismal weather, must assuredly possess the grit which makes for greatness. Such are the trying times of our lives, but fortunately the silver lining often follows the dark cloud, while this in turn gives place to the inspiring sunshine which sets the whole universe in motion.

The sunshine of spring is anxiously longed for by all classes of the community, but gardeners have special reasons for doing so, because through its influence the plants and crops under their care flourish with a vigour which makes the heart glad. Early forced fruit and vegetables which recently have been almost at a standstill, now show considerable progress as each day ends, and the leaves begin to lose the pale coloured growth of winter, and assume a rich green tint. With so many illustrative facts before us concerning the power of sunshine and lengthening days upon vegetation, the question naturally arises, How comes it that sunshine produces such wonderful results?

Not only gardeners, but almost any adult, knows instinctively that heat and sunlight are potent forces in making the earth "smile with plenty" when moisture is also present, but few could definitely explain why such is the case. Although plant physiologists have not yet drawn from Nature the whole of her secrets in regard to the matter, they are able to afford us some enlightenment. They tell us that as the temperature is raised by the sun's rays, the sap of trees and plants, which thickens under the influence of cold, changes to a thinner liquid that has a more rapid circulation. This, however, is only one part—the smallest part—of the various forces which "King Sol" sets in motion. Vegetation derives a vast amount of food from the atmosphere, and, under the influence of sunlight the progress of absorption, decomposition, and exhalation is greatly accelerated. The carbonic acid gas, which is absorbed from the atmosphere through the pores of the leaves, is then quickly decomposed, the charcoal retained by the plants, and the oxygen returned to the air. Thus the atmosphere which surrounds us is being continually vitiated by animal life and purified by rapid growing vegetation.

There is also another phase in connection with the matter which should be touched upon—viz., the influence sunlight exerts upon the soil. The warm air being pressed into the soil causes roots to extend with great rapidity, and each tiny root-hair within reach of the atmosphere draws some good from it—good in the form of gases which unite with the acids in the soil.

The above facts, I think, should show us in some degree the subtle laws by which Nature sets her forces in motion by the aid of sunshine, with such wonderful results. They show us also that the time-honoured practice of frequently stirring soil during the warm days of spring is founded on a scientific principle, though probably in the majority of cases only practised because observation showed the good results which followed. The loosened surface lets in the warm air more freely than that which is left undisturbed; and, as it also prevents the moisture beneath from evaporating, the three great essentials—warmth, air, and moisture—are found in combination, and under such circumstances rapid growth will ever be made provided the soil is fairly rich.

Work in the open air has recently been almost at a standstill, but a "turning movement" should soon bring the soil into that desirable condition in which it may be worked with advantage; then each moment of daylight will be precious indeed for all real gardeners who strain every nerve to make good past delays. All experienced men, however, know well how fatal it is to let over-anxiety force their hands to disturb the soil while it is wet and clammy; the work cannot then be either well or quickly performed, and the soil, instead of crumbling under the influence of wind and sunshine, will be converted into hard lumps, which will take a whole season to get right again. Compare the results obtained from seeds sown under various conditions. The man who makes a point of sowing his Onion or Carrot seed on a certain week, when that time arrives anxiously looks out for a break in the weather, and during the first fine day makes a great effort to get the work done, although the soil may not by any means be in an ideal condition for working. By dint of misapplied perseverance the task is accomplished, but the wetness of the soil to a great extent seals it from the action of air and sunshine, and when fine weather does come the seeds sprout slowly, and the young plants are pale in the leaf, all because warmth and air have not freely entered the soil.

The more level-headed gardener waits till a settled sunny day arrives, when the soil is dry upon the surface; willing hands then

quickly loosen it with hoe or rake, it is left for an hour or two to dry still further, when the drills are drawn and allowed to bask in the magic sunshine for a time before the seeds are sown. When all is completed the surface is loose and crumbly, the air and sunshine enter freely, and when the seedlings push through the soil they are sturdy and strong, and grow with far greater rapidity than those sown a week or two earlier under less favourable conditions, and at the time of harvest give infinitely better results.

Such examples might be multiplied indefinitely, but for the present I think enough has been advanced to show, in the glorious sunshine—when we get it—the gardener has a willing servant, and those who have the happy "knack" of turning that service to the best account will ever press onward in the "gentle art, the art which gladdens the eye with beauty, and fills our stores with plenty."—ONWARD.

ROBINIA HISPIDA.

A SHORT time ago a writer of some interesting notes on flowering trees mentioned the Rose Acacia (fig. 54) and others of the Acacia family being broken down by the weight of the flowers. I can speak with feeling, especially in regard to this one. I have this season had fine plants of it blown out at the point where the shoots leave the main stem, but this is not so much due to any inherent weakness of the species as to the ridiculous method of grafting—and badly grafting—it on half-dead stems of the Thorn Acacia. Worked low down the plant would make a strong, though perhaps not exactly a straight stem; but trees I purchased a year or two back were so badly worked that they had the crevices stopped up with grafting wax before they came into my hands.

What wonder if such trees blow out; yet they come from what is considered a first-rate nursery. The same correspondent called attention, too, and rightly, to the fact that André's Genista will not thrive on some soils. Here I have a great difficulty in getting it to move, but I should like to recommend the Spanish Broom, *Spartium junceum*, to anyone who fails with the former. It is a beautiful plant, and very free growing, but hares and rabbits give it no quarter if they can reach it.—H. R. RICHARDS, *Coldham*.

POLYGONUM BALDSCHUANICUM.

A VERY interesting article in a recent number of the "Revue Horticole," by M. Dauthenay, upon this Polygonum leads one to think that it may advantageously be again brought before readers who admire climbing plants. There is certainly no scarcity of these indispensable aids to the beauty of the garden, but we have few, if any, at all like *Polygonum Baldschuanicum* in general appearance. I do not like to say that I care for the tone of colour of its foliage, although I admit that many persons do, but its flowers are so attractive, and its general effect so good, that one is disposed to overlook any faults it may have. Until recently it has been too high in price to induce many to grow it, but now that growers have apparently mastered its propagation plants have become much cheaper. Last autumn I obtained a good plant from the continent at a moderate price.

I was glad to possess the details about its introduction. The article does not say, however, when it found its way into the Royal Gardens at Kew, where I saw it last year. It was, it appears, found by M. Regel in Turkestan in 1882, and was described and figured in the "Transactions of the St. Petersburg Botanic Garden," vol. vii. It appears that it had been named *Atraphaxis nov. sp.*, but that M. Regel had convinced himself that it was a *Polygonum*. It reached the Museum of Paris in 1892. There, as at Kew, it is perfectly hardy. It grows to a height of 12 or 15 feet, and when grown up a pole makes a pretty pyramid of cordate foliage freely covered with bunches of white flowers prettily tinged with rose.

While this method of growing *Polygonum Baldschuanicum* may be convenient for a botanic garden, it is too formal for most private gardens, and I think it could be grown with better effect up a tree or against a trellis or wall; not, of course, in a formal way. It does not appear to be fastidious as to soil, but in order to make it grow freely—an almost needful thing if we want to enjoy the full beauty of climbing plants—it ought to have a station well prepared for it by deep digging and free manuring. It has the reputation of being a difficult plant to propagate, and many have failed with it. It is however, said to be easily increased by taking shoots of the past year and after cutting them into lengths, laying them in pots or pans with a thin layer of silver sand above. These pots or pans are placed in a moderate heat. While I am not prepared to place it in the highest rank of our climbing ornamental plants, it is superior to many that are grown at present.—S. ARNOTT.

RETINOSPORA ERICOIDES.

RETINOSPORA is a generic title which has been given to a class of Conifers that have little in common with each other except superficial appearances. Under the name of *R. ericoides* three plants are, or have been, commonly known, one of which is a North American species of *Cupressus*, and the other two varieties of two species of *Thuia*, one of which is a native of North-Eastern America, and the other of China and Japan. The first of these is *Cupressus thyoides*, which was formerly known as *R. ericoides*, but of late years this has been dropped in favour of *Chamaecyparis sphæroidea*. It is a native of N. America, and is commonly known there as the White Cedar, though this, like most other common names, is entirely misleading. It forms a tree of

less flattened, and the leaves more pointed and less appressed to the stems. But in many plants of this variety, more especially those of some age, a second kind of growth can be found lower on the branches and near the main stem; this growth differs little, if any, from that of the var. *ericoides*.

The third is *T. orientalis* var. *ericoides*, which is very much like the preceding both in point of size and general appearance, but the winter tint is much more vivid, and the plant has rather more of a spreading habit. The leaves also are set at nearly right angles to the stem instead of pointing forward, and are distinctly glaucous on the back, and have also a faint glaucous tint on the upper surface. The connecting link between this and the type is not very clearly shown, though traces of it can be seen in the vars. *intermedia* and *pendula*.

FIG. 54.—ROBINIA HISPIDA.

columnar outline, which in this country has attained a height of about 40 feet so far, but with time will probably reach 60 or 80 feet. Its branches are short and much divided, especially at the extremities, and the leaves are small and closely adherent to the stem. It can be easily raised from seed, which is freely produced in this country.

The second is *Thuia occidentalis* var. *ericoides*, which is a very different looking plant to its parent species, the well known American *Arbor Vitæ*, as it only grows about 7 or 8 feet high, but is seen at its best as a young plant of about 2 or 3 feet, when it forms a feathery-looking specimen, which in winter assumes a pleasing bronzy tint. In summer it shows little of this colouring, being nearly or entirely green, but changes on the approach of winter. The leaves are small and point towards the ends of the branches, and are green, or slightly glaucous, on the back. Though this plant differs so much from *T. occidentalis* in general appearance and habit, yet the connection between the two can be clearly seen in *T. occ.* var. *Ellwangeriana*, in which the ordinary growth is smaller than in the type, the secondary branches

These two latter plants, known as *R. ericoides*, are perhaps the most useful of the smaller-growing Conifers, as they are easily propagated by cuttings, are perfectly hardy, and can be used for so many different purposes of decoration. For window boxes, the filling of bords for the winter, or for the conservatory they are invaluable, as they have a distinctive beauty of their own that is very effective, and which is seen at its best during the winter months.—C.

PLANT DOCTORS.—A writer in a contemporary urges the need of a new class of educated physicians, whose business shall be the care and cure of disease-threatened and disease-stricken plants. "The time will come," he says, "when every agricultural district will have its plant doctor." He even foresees the development of specialties by plant doctors just as by other physicians, so that in many difficult and obscure cases of disease affecting valuable plants the services of such specialists will be employed.

THE YOUNG GARDENERS' DOMAIN.

BITS FOR THE BOTHY.

ON THE MARCH. (Continued from page 166.)

En route for the promised land of a young gardener's hopes and aspirations, every stage gives deeper and wider views. 'Tis as if the morning of life in breaking through a haze pregnant with possibilities advances with a continually lifting horizon. On that horizon lays the goal of ambition, ever tempting a man onwards and upwards.

"It fleets on the vision, deluding the view;
Its banks still retire as the hunters pursue."

"This is a queer kind of logic," some may think. It is a natural thought. One particular point, however, has to be impressed, even to the risk of wounding a young soldier's *amour propre*, that is never to feel quite satisfied with your efforts—with yourself. No great man or good man ever did. There is a something in the human breast, and it has been there since man was placed on earth, prompting him to use the highest step he ever reached for the purpose of stopping higher still.

Self-satisfaction is as contemptible a thing as self-pity, and where a growth of either crops up it may be rightly concluded that something has gone wrong; too often the fault of the trainer it is feared, for "as the twig is bent the tree's inclined." You do not, perhaps, quite understand this yet. That is natural, too. Would that time, and space, and power permitted such things to be placed in a clearer light before you to prevent any young recruit who is now manfully stepping out from perverting the incentive, which it is, into a stumblingblock, that it may appear. The most one dares to hope is that it may be the germ implanted in the fresh medium of a young heart to grow into the highest and noblest of thoughts and actions; then—"what then?" you will ask, after showing that the ideal still lays a little beyond—the great beyond. Then, "In the temper of the invisible mind, the godlike and undying intellect. There are distinctions that will live in heaven."

There are, there should be, quiet moments in the bothy when the day's work is done, when you have not only been true to your master, but true to yourself in the self-imposed task, when it is good to elevate the mind above the comparative smallness of its surroundings, and enjoy in the very fetters of your flesh, as Epictetus did, the highest and noblest of freeborn thought. Do so. It shall one day place you high in the ranks of gardeners, and higher still in the ranks of men. March on, then, my young recruits!

As physical drill brings every muscle into play, so mental exercise develops the faculties to a degree of which few recruits are aware. Do not grumble because you are deprived of the more showy advantages that many youths possess, and in order to be saved from mediocrity you are compelled to work out your own salvation. Self-education is the finest form of education extant, although it is the fault of a few and the misfortune of many that they will not or cannot see it. That the method is not an easy one is admitted, but the harder the nut the sweeter the kernel, when you have cracked it yourself. Crammering is a mechanical process, and although the recipient may shine on an examination paper, one is sometimes surprised in a little conversational rubbing of the highly polished article to find it is only veneer after all.

Halt! This is necessary in order to mark time. To follow any course without a method is to court a muddle, and it is of the highest importance that censorship of some sort should regulate a recruit's efforts, more especially in considering that he is a freelance in bothydom. Necessary? Nay, it is insisted, that each recruit laiks periodically for inspection. How is it to be done? Will he trot himself out for a comrade's criticism? No; that won't do. Or for his officer's inspection? That might do, but may not be expedient; and, after all, there are motives of delicacy, perhaps, forbidding even those who are nearer and dearer from coming between a boy and his conscience. We will say, for example, that Tom Jones is being reviewed, but, as a matter of fact, the best part and the worst part (matters must not be minced) of Tom Jones is shut up inside, and this is the part we want to see. Each man, each boy, leads a dual life; the outer part is for the world, the other, the inner part, is not, in this sense, for the world; it is sacred. You, young reader, are for the moment Tom Jones; you take, as you ought to do, a keen interest in his welfare, and you are going to criticise his work. Please make these inspections weekly, monthly, quarterly, and yearly, to correspond with the periodical plans.

For the weekly inspection a few minutes will do, and this is how to do it. You, as Tom Jones the outer man, will put Tom Jones the inner man through his facings—call him to account for the week's work. Spare his feelings by privacy if you will, but otherwise be more inclined to rap his knuckles for any shortcomings than to pat him for just doing a plain duty. He has not, perhaps, carried out his weekly plan as he should have done. Why not? you will ask, sternly and uncompromisingly. "Oh! on such a night the boiler burst; all had to turn out." Right; that's a real excuse; let him off. Another night he was "in bad form; felt a bit shaky; couldn't settle down to study." Don't let him off, shake him up, and record all excuses, good and bad, in the diary. Long before the end of the year, before the grand review, T. J. has, perhaps, become very lax, and perhaps "dropped off" altogether. "Will turn over a new leaf at the new year." Don't believe him; you ought to know him better. Such cases are hard to cure; to prevent them is the earnest desire of—THE OLD BRIGADIER.

(To be continued.)

FREESIAS.

FREESIAS are amongst the most popular and useful plants we have for early spring flowering. The graceful flowers are most valuable for vases when cut with as long a stalk as possible, or the plants may be very effectively used for the conservatory, with small Ferns and Grasses dotted in between them. Freesias should be potted in 5-inch pots at the end of August to flower in January, putting six to eight bulbs in a pot. They succeed well in a compost of two parts of loam, one part of leaf mould, and one part of spent Mushroom bed refuse, with plenty of coarse sand. The pots should be clean, and have ample crocks placed in for drainage, with some moss on the top to prevent the particles of soil mixing with the drainage, which would soon become choked and the soil sour, and the roots perish.

After potting, the Freesias should be stood on coal ashes in a north frame, and covered with cocoa-nut fibre refuse until well rooted, when they must be moved to a frame, where they will get plenty of light and be near the glass. The plants must never be allowed to become dry at the roots, and the structure containing them should be well ventilated day and night. When the weather becomes cold they must be removed to a shelf in a cool greenhouse, where they will get abundance of light and fresh air. The plants should be neatly staked with small sticks or bamboos. I think it much better to give each bulb a stake than to tie them in a bundle, as one often sees them. When they begin to show flower spikes they should be fed about twice a week alternately with weak diluted cow manure and clear soot water.

After Freesias have done flowering, water must be gradually withheld and the bulbs dried off. The pots ought to be stood where they will be free from moisture, and with full exposure to the sun. This is very important, because if the bulbs are not well ripened by the sun success will not be fully attained the following season.—F. W. P.

DRAWING FOR YOUNG GARDENERS.

MANY bothytes and young gardeners are situated in localities far from towns, and, therefore, cannot attend lectures, evening classes, and things of that kind. Then some have not the energy or inclination for a course of hard study such as is entailed by entering for horticultural or other examinations. And who does not find ordinary reading tiring if continued without cessation through the long hours of a winter evening?

Yet young men, and especially young gardeners, are crammed full of onergy, and must be doing something. To such I would suggest that they take up drawing, an amusement, which, if persevered in, will prove profitable and instructive, and, moreover, one that will become fascinating, after the rudimentary stages are passed. I say that it is instructive, for it trains the eye and develops the faculty for observation. In my own case, for instance, I have noticed many little points about groups of trees and shrubs, masses of flowers, landscape scenes, and structures, that I should never have observed had I not taken up drawing as a study. And these apparently insignificant details might prove of the utmost importance in any laying-out or planting that I may be called upon to do in the future. Every gardener should be an artist, more or less, and, though true artists are born, not made, much may be learnt by steady application and observation.

Beginners naturally like to draw from printed copies, as it seems easier, and this is, I think, advisable, until some slight proficiency in the art is gained. But it should not be kept to too long. Very beautiful copies of flowers, fruit, and landscapes are to be found in some of Vere Foster's books (price 2d. each, procurable in any town or by post); there are also numbers of text books, ranging in price from 2s. upwards; any friendly schoolmaster would advise as to the purchase of these.

But the real delight comes when one dispenses with books, and can sit down and draw from nature. There are plenty of objects all around us—individual flowers, plants in bloom, trees in their summer and winter garb, and so on in endless variety. What more beautiful and yet comparatively easy subject could one choose than an Arum lily (*Richardia æthiopica*) in flower? Again, how interesting are the wonderful changes of light and shadow on a tree in full leaf. Have you ever noticed the changes in this way, wrought by the varying lights of a summer's day? You see a tree in the distance, and say that it is an Oak, an Elm, or Beech as the case may be. Have you ever stopped to think how you can determine this, not being sufficiently close to see the shape of the individual leaves? Could you explain that one tree differed from another in outline, or in the mode of growth or effect of light and shadow of its foliage? Drawing would teach you all such things as these.

Then there is another valuable kind of drawing, which needs the use of the rule, compass, and square. I refer to plan, scale, and perspective drawing. This, perhaps, is not quite so interesting, unless one has a turn for mathematics, but may prove extremely useful. Subjects for beginners can be found in houses, kitchen garden, and bothy which they occupy and work in. Ground plans and front and side elevations of these can be worked out, and thus a number of little structural details will be observed and mentally noted, which may prove of great use at some future time.

I may at some future date have more to say with regard to the tools required, and my own method of working. And who can tell? perhaps some of us young scribes may be so honoured as to, some day,

see our artistic efforts appear in the pages of the *Journal of Horticulture*, in pictorial explanation, may be, of some point we cannot make lucid in words. I am afraid what I have written is somewhat halting and imperfect for so great a subject, but if it arouses an interest for drawing in young gardeners my article will have done its work, and I am sure they (the young gardeners) will profit.—S. X.

FRUIT FORCING.

Cucumbers.—The night temperature in houses may be increased to 70°, but 5°, or even 10° lower on cold nights, is more favourable, watering more freely and increasing the atmospheric moisture. In the daytime 85° to 90° from sun heat should be allowed, running up to 95° or 100° when the weather is favourable after closing. Thin out the growths once a week, removing the old and superfluous, but not carrying this out excessively at one time. Stop, tie, and otherwise regulate the shoots as required, removing the tendrils and male blossoms. Supply lumpy loam previously warmed, and sprinkle over it a little soot.

Cucumbers in frames with the beds made up some time will need good linings, and when the heat is up see that there is no rank steam in the frame, preventing it by ventilation. A night covering will be necessary to maintain a night temperature of 65° to 70°. Admit a little air at 75°, and permit the temperature to increase to 85° or 90°, closing so as to maintain those degrees, or even advancing to 95°. Add a little more soil as the roots spread on the surface or protrude through the sides of the hillocks. Stop the leading shoots 1 foot from the sides of the frames, and the laterals at one or two joints beyond the show for fruit. Attend to training and pegging the shoots, being careful not to overcrowd them. In watering do not wet the foliage more than can be helped, taking care to have it at the same temperature as that of the beds. A sowing of seeds may be made to raise plants for growing in pits and frames that have been occupied with Radishes or early Potatoes. In four or five weeks the seedlings are ready for planting, and will come into bearing in or about a similar time, affording a supply of fruit during the summer.

Melons.—The earliest plants are now well advanced, and if stopped when they have extended about two-thirds across the trolis laterals follow, with fruit showing at the second or third joint. To insure a good and prompt setting of the fruit it is necessary to afford a bottom heat of 80° to 85°, and sufficient water only at the roots to prevent flagging. This will arrest growth, and in combination with a rather dry atmosphere, a circulation of warm air passing through the house will favour the production of pollen. When this is ripe, fertilise the pistillate blossoms as they expand every day, and stop the shoots at the same time one joint beyond them. If a succession of fruit be required in the same house, deprive some of the plants of the flowers that appear on the first laterals. Stopping these at the first or second joint will cause the sub-laterals to show fruit, which will be rather later and finer, owing to the increased vigour of the plants.

The plants in pits and frames will require attention in training and regulating the shoots, removing every alternate lateral, and applying water sufficiently to maintain a steady growth, always of the same temperature as that of the bed. As soon as successional seedlings are ready plant them out, and pot others as they become large enough. Seeds may be sown to provide plants for pits and frames as they become cleared of Radishes or early Potatoes, about five weeks being required to secure strong plants.

Vines.—*Eyes.*—Those inserted in February will now have rooted, and should be shifted into 6-inch pots as soon as the roots reach the sides of the smaller pots, placing them on slate shelves over the hot-water pipes. Water only to maintain a steady supply of moisture in the soil, erring, if at all, on the dry rather than the wet side. Syringe well amongst the Vines, but not too forcibly. Pinch the laterals to one leaf, also sub-laterals as made.

Cut-backs.—The canes cut back last month and placed in heat will now be fit for shaking out, repotting, or placing in the fruiting—12-inch pots. Keep them close and moderately moist until they are established. Train the canes near the glass so as to insure thoroughly solidified growth as it is made. Clean pots, and efficient drainage of clean crocks should always be provided. Turfy loam, rather rough and moderately moist only, with a pint of bonemeal, a quart of wood ashes, and a pint of soot to every bushel of loam, forms a suitable compost.

Early Forced Vines in Pots.—Canes started last November will now have the fruit stoned and taking the last swelling. The Vines, therefore, must not sustain any check through dryness at the roots or want of food. Surface-dress with rich material, and supply liquid manure until the Grapes are evenly coloured, then afford water only sufficient to preserve the foliage fresh and the fruit plump.

Early Houses.—Thinning the berries should be kept well in hand, commencing as soon as those likely to swell freely can be detected, and as a rule thin them well in the interior of the bunches, leaving the berries with room to attain their full size without wedging, and yet so full as not to fall out of shape when placed on a dish. Liquid manure applied to inside borders will materially assist the swelling of the Grapes after they have been thinned, but it is best to vary the diet, giving a top-dressing of some approved fertiliser about every three weeks. A liberal supply of atmospheric moisture is also necessary, and if moderately charged with ammonia it is beneficial to the Vines and inimical to red spider. It may be secured by occasionally sprinkling the border and paths with stable and cowhouse drainings duly diluted, or guano water, 1 oz. to a gallon of water, or better still supply a mulch of sweetened horse droppings, a little at a time over the whole border, but too much at once will prejudicially affect the foliage. Sharp winds require care in ventilating, air being judiciously admitted in such weather, so as to avoid sudden changes, and the consequent crippling of the foliage and rusting of the Grapes. A night temperature of 60° to 65°, 70° to 75° by day, and 80° to 85° from sun heat is suitable.

Succession Houses.—Disbud and tie down as the growths advance, stopping them two joints beyond the bunch where the space is limited, but where there is space allow a greater extension before stopping. Remove the laterals from the joints below the show for fruit except from the two basal leaves, which may be stopped at the first leaf, and one afterwards as produced. The laterals above the fruit may be allowed to make such growths as can have exposure to light without crowding, and then be stopped, keeping them closely pinched afterwards, as well as in the case of those not having room for extension. Remove all superfluous and ill-formed bunches of the free-setting varieties as soon as those most promising for the crop can be determined.

THE KITCHEN GARDEN.

Wet Weather and Seed Sowing.—Such a long spell of wet sunless weather following a heavy fall of snow has had the effect of saturating the soil, and garden work has been almost at a standstill for some time past. Especially bad is so much rain for the heavier clayey soils, and it will be most unwise to attempt working these till such time as they are considerably drier than at present.

Peas.—If seeds of early varieties were sown in the open ground prior to the fall of snow, and the plants are not yet showing through the soil, an examination should be made. If the seeds have germinated at intervals, only enough plants ought to be raised under glass to fill the gaps, while if the row promises to be so thin as to be not worth preserving, sufficient plants should be raised to form the requisite number of rows, or otherwise no very early dishes will be obtained. Sow the seeds moderately thickly in 3-inch to 5-inch pots; place in heat to germinate; harden the plants before they become leggy, and on the first favourable opportunity plant out, keeping the balls of soil intact. In this way early if not very heavy crops should be obtained. Sow more seed in the open directly the ground is fit to receive it.

Broad Beans.—Much that has been advanced concerning Peas also applies to these. As it happens Broad Beans are not so much appreciated as Peas, and only where they are wanted extra early need plants be raised under glass.

Broccoli.—Veitch's Autumn Protecting, and which is only a little inferior to Autumn Giant Cauliflower, forms an admirable succession to the latter, and pays well for raising and getting out early. Seeds sown in the open germinated in due course, but the seedlings quickly fell a prey to slugs which could not well be kept off in the wet weather prevailing. Enough plants for most gardens can easily be raised either in a frame or in boxes or pans of soil in gentle heat.

Brussels Sprouts.—Long rows and many beds of autumn raised plants have been decimated and in some cases cleared off by slugs, market growers complaining most of these losses. Seed sown early in February and protected by straw germinated surprisingly well, but the plants are disappearing fast, soot and lime washing off as fast as applied. A portion at least of the plants required ought to be raised quickly by sowing either on mild hotbeds in frames, protecting with either lights or mats, or, if only a comparatively few plants are required, as advised in the case of Broccoli.

Cauliflowers.—Plants under hand-lights and others that will be moved into sheltered borders or disposed at the foot of south walls will not grow well at first, and the probability is will, in many cases, "button," or form tiny hearts prematurely. Anyway it will be a good plan to quickly establish a number of small plants in 3-inch pots, keeping them on shelves in cool houses or in frames till strong enough to be hardened and planted out. The earlier varieties should be selected for this purpose. More plants of early main crop and autumn varieties ought also to be raised under glass.

Borecole.—There is no necessity to raise any plants of these under glass. A favourable opportunity should be selected for sowing seed of Borecole, successional (not late) Broccoli, Sprouting Broccoli and Savoy in the open some time in March.

Cabbages.—Autumn planted Cabbages are fairly promising, and at present there are few "bolting." It is an important crop, and if many failures are anticipated early raised plants may well be established in small pots under glass, duly hardened and planted out where the gaps

occur. If seed sown early in the open is not giving many plants more seed ought at once to be sown under glass, the plants properly treated heartening in early next summer.

Carrots.—Those who have sown seeds on mild hotbeds with or without the protection of glazed lights, will most probably have good reason to be satisfied with the results of their labour, as the earliest open air crops will be later than usual and thin. It is not yet too late to utilise a mild hotbed for an early crop of Horn Carrots.

Radishes.—Seeds sown in large beds and protected with straw, market growers' fashion, have germinated most satisfactorily. The plants should be dusted over as often as necessary with soot and lime to keep off slugs, and the covering of straw be hovered over them every evening, this protecting them from cold winds as well as frost. Sow more seed and treat similarly.

THE BEE-KEEPER.

THE LATE SPRING.

IN consequence of the severe weather experienced during the past month vegetation is very backward. It is, therefore, not surprising to find a great scarcity of early spring flowers throughout the Midlands. Usually at this date—the end of February—we have had them in abundance. Now the only flowers to be found in the open borders where no protection has been given are the Winter Aconites. Although the blooms were fully expanded before the heavy fall of snow and the severe frost came, they do not appear to have suffered in the least. In sheltered positions Snowdrops are just coming into bloom. These and a few Christmas Roses are the only hardy flowers at present.

Having in past years planted many thousands of bulbs and plants for the adornment of the garden, which are bright in their season and beneficial to the bees, we are enabled to form a fairly correct opinion as to their early flowering or otherwise. Last year at this date there were large masses of Crocuses in bloom; also *Arabis alpina*, *Myosotis dissitiflora*, Primroses, Violets, and the earlier sown Wallflowers were showing their first flowers.

After the excessive rainfall experienced during the past month the land will be in a wet and cold condition for some time to come; and owing to the scarcity of flowers the garden will doubtless have a somewhat gloomy appearance. The plants, however, will bloom with greater freedom, and as the days lengthen the sun will be more powerful. This will be an advantage to bee-keepers, as should the weather be favourable bees will make great headway, as there will be an abundance of pollen. Much of this is wasted early in the season when the flowers are early and the bees have not commenced breeding.

POLLEN-PRODUCING TREES.

The early spring is a suitable season for planting either hardy trees, shrubs, and plants, which will not only beautify the garden or woodland, but will benefit the bees. Planting should not be attempted until the land is in fit condition. Amongst early pollen-producing trees we would mention the common Palm Willow. It is one of the earliest and best with which we are acquainted, lasting a long time in good condition. It may be planted in any out of the way damp position, and will thrive where only the *Salix* will succeed. The common Barberry may be planted in the shrubbery or woodland, and being a dwarf growing shrub it will not take up much room. It produces an abundance of pollen at a season when it is most useful to the bees, and is usually in flower before the Palm Willow is quite over.

The above are succeeded by the Box tree. Although this is not usually classed as a pollen producer, it is really one of the best for late spring. We have numerous bushes near our apiary; some of them are of a great age, and during the time they are in flower they are much visited by the bees. Unfortunately, they do not bloom in a young state. The same fault may be found with the Lime tree, one of the best late honey-producing trees in this country. We would recommend the Lime tree to be planted extensively, not only for the above good quality, but also for its handsome appearance, either as a single specimen or as an avenue tree.

The Almond should not be omitted, as when planted singly in prominent positions they have a very showy appearance whilst in bloom, and the bees work freely on the blossoms. Apples, Pears, Apricots, and Plums, as well as the various small fruits, are much frequented by the bees, and need no description here. Of late years we have planted the Siberian Crab and its varieties as single specimens. These have a handsome appearance whilst in bloom, and when they are laden with fruit, as well as being beneficial to the bees.—AN ENGLISH BEE-KEEPER.

All correspondence relating to editorial matters should be directed to "THE EDITOR," 12, Mitre Court Chambers, Fleet Street, London, E.C. It is requested that no one will write privately to any of our correspondents, seeking information on matters discussed in this Journal, as doing so subjects them to unjustifiable trouble and expense, and departmental writers are not expected to answer any letters they may receive on Gardening and Bee subjects through the post. If information be desired on any particular subject from any particular authority who may be named, endeavour will be made to obtain it by the Editor. Letters of inquiry must be accompanied by the names and addresses of the writers, but these will neither be published nor disclosed when initials or *noms de plume* are given for the purpose of replies.

Correspondents should not mix up on the same sheet questions relating to Gardening and those on Bee subjects, and it is convenient when each question is written on a separate sheet. All articles intended for insertion should be written on one side of the paper only; and the name and address of each writer must be known by the Editor, though not necessarily for insertion. We cannot, as a rule, reply to questions through the post, and we do not undertake to return communications which, for any reason, cannot be inserted.

Tulips not Opening Satisfactorily (*Temperance*).—The plants are in good condition at the roots, the bulbs quite sound, the stems and foliage healthy, and there does not appear any defect of condition calculated from a cultural point of view to account for the flowers not expanding properly. One of the blooms had very thin and even shrivelled petals, but beyond that no trace of disease was discovered. The other flower was more or less decayed, and on parts there was a mould, named by fungologists *Botrytis candida*. Whether the cause or the consequence of the condition of affairs, it is injurious to blossoms and even fruits of Strawberries and many other flowers in a damp atmosphere. The only preventive, for there is no remedy, is to avoid a close stagnant atmosphere by judicious ventilation. The weather lately has been such as not to admit of much ventilation, hence the damp and favouring conditions for the development of the fungus.

Cucumber Plant Unsatisfactory (*Cross*).—The specimen has been carefully examined, but no trace of animal or vegetable parasite discovered in the plant or on the roots. The young rootlets, however, are more or less brown and dead, but whether caused by deleterious bodies in the soil, over-watering, or something organic we are unable to determine at the present stage. The fibrelets are rusted and the plant suffers in growth through loss of imbibing power. The rust may have been caused by water containing an excess of iron, or the water may have been too cold and given a chill. A sprinkling of air-slaked chalk lime and soot in equal parts by measure, mixed, would, we think, improve the soil, using 4 ozs. per square yard on planted-out stock, or half a pound may be mixed with a cubic foot of soil before planting, or sprinkle occasionally on the surface after planting, the watering sufficing to wash it in. A good handful of the mixture per square yard is sufficient at a time, and about every three weeks often enough.

Pæonies from Seeds (*C. B. T.*).—The seeds you bought were probably good. The proper time to sow seeds of Pæonies is in September, in pans containing good loamy soil, covering the seeds with fine soil a little deeper than the diameter of the seeds, placing in a cold frame or pit, and keeping moist. Some of the plants will appear the first and others the second spring after sowing; therefore, the seed pans should be kept until the autumn of the second year, when you will have all the plants that will appear, and they may then be pricked out in good rich soil in a somewhat sheltered situation outdoors, planting them in rows a foot apart, and allowing 6 inches distance between the plants. A mulching of leaf soil or well decayed manure after planting will act as protection, and assist the growth another season. After they have grown a year or two they may be planted out where they are to remain, or they may stay in the original bed to flower. Transplant with all roots possible. You will see that raising Pæonies from seed is not a quick process, and most persons prefer to purchase plants, which are not expensive, from a hardy plant nurseryman.

Occupation of Man's Time in Houses (W. J. C.).—Everything depends on the sizes of the Orchids, and upon the dimensions of the vineries and house of Carnations; but assuming there are three houses or compartments of Orchids, and the sizes and dimensions respectively are ordinary, there will be plenty of work in the six structures for one man. Of course there will be slack times, as when the Orchids are resting; and, on the other hand, busy times, as when the general potting of the Orchids and thinning of the Grapes demand prompt attention, so that a more or less "give and take," coming we presume under "other jobs," has to be practised, to mutual advantage.

Browallia elata (D. C. C.).—The seedlings should be potted either singly or three in a pot when they are large enough to handle. The latter make fine masses for conservatory or greenhouse decoration. After potting they should be kept on a shelf near the glass in a house with a gentle heat, and syringed every morning and evening to prevent the attacks of insect pests. They should be stopped when a few inches high, repeating when they have grown a few inches, so as to keep them dwarf and bushy, it being necessary to stop them about three times to have well furnished plants. Supply liquid manure, not too strong, after the flower buds appear. They require plenty of light, so as to insure thoroughly solidified growth and a floriferous habit.

Chrysanthemum Cuttings Damping (Perplexed).—The cuttings have simply damped off by an excess of moisture, the soil being wet to soddenness, consequently sour. This has caused the destruction of the tissues, and the decay has spread upwards, so that the cuttings are black level with the soil. The only preventive is to use sweet loam with a third of well-decayed leaf soil and one-sixth of sand, mixed, for filling the cutting pots, surfacing them with the latter, and using a blunt dibbler for inserting the cuttings, so that some of the sand is forced down for the base of each cutting to rest on; a little of the sand will drop about each cutting, or it can be pushed into the hole before closing the soil. With this care and attention to keeping the soil moist, but not overwatering, every cutting ought to root and be healthy.

Weeds on a Lawn (M. P.).—The cause of lawns being thus infested is usually poverty of soil, and a good dressing of short manure may be applied now. In early April scratch the lawn well with an iron rake, and during the earliest prospect of rain afterwards, sow some lawn grass seeds so as to thicken the grasses, distributing most seed on the bare places. If you have no manure apply soot, wood ashes, and quicklime, in equal parts, all dry and well mixed at the rate of a peck per rod, and rake it well in. The manure or some rich compost would be the more effective, as it is ammoniacal or nitrogenous matter, which is necessary to encourage the growth of the grass, and enable it to gain the ascendant. A dressing of soot or some artificial manure would be of great benefit applied at the time of sowing the grass seeds, or nitrate of soda at the rate of 1 lb. per square yard.

Protecting Apricots from Frosts (W. H. S.).—As you want a material that may remain over the tree constantly you can employ a double thickness of herring net. This will break the force of cold cutting winds, arrest and prevent the settling of dew on the tree, and thus comparatively dry, the blossom and young fruit will be preserved from injury. To keep the net from the tree, poles should be set in the ground about 6 feet apart and 18 inches from the wall. They should extend about a foot higher than the branches, and rest against the surface of the wall, securing them with string or nails. The net should be fastened to the wall just above or level with the top of the poles, and let down over the tree, resting on the poles, and reach to within 18 inches of the ground, but be kept clear of it, securing the netting to the poles at the bottom. The netting must extend over the tree sideways and be secured to the wall on both sides, being drawn taut and kept clear of every part of the tree. It should be put up when the first blossoms show colour—that is, appear white—and remain until the weather becomes warm and settled in May, or sufficient foliage has been produced to protect the fruit.

Names of Plants.—We only undertake to name *species* of cultivated plants, not wild flowers, or varieties that have originated from seeds and termed florists' flowers. Flowering specimens are necessary of flowering plants, and Fern fronds should bear spores. Specimens should arrive in a fresh state in securely tied firm boxes. Thin paper boxes arrive in a flattened state. Slightly damp moss, soft green grass, or leaves form the best packing, dry wool or paper the worst. Those arrive in the best condition that are so closely or firmly packed in soft green fresh grass, as to remain unmoved by shaking. No specimens should be sent to rest in the post office over Sunday, on which day there is no delivery of postal matter in London. Specimens in partially filled boxes are invariably injured or spoiled by being dashed to and fro in transit. Not more than six specimens can be named at once, and the numbers should be visible without untying the ligatures, it being often difficult to separate them when the paper is damp. (*A Weekly Reader*).—Three pretty forms of *Odontoglossum Rossi*; No. 3 resembles *O. R. cœrulescens*. (*J. S.*).—1, *Dendrobium speciosum Hilli*; 2, *D. pallens*; 3, a poor form of *Cattleya Trianae*. (*Young Gardener*).—*Æschynanthus cordifolius*. (*C. T.*).—1, *Helloborus olympicus*; 2, *Ornithogalum nutans*; 3, *Cardamine hirsuta*; 4, *Dielytra eximia*; 5, *Senecio Ghiesbreghtii*. (*A. H. D.*).—1, A well spotted but poorly shaped form of *Odontoglossum crispum*; 2, *O. luteo-purpureum*.

SCIENCE AS APPLIED TO NOXIOUS WEEDS.

LET the early summer months be upon us, and we shall take up no agricultural paper without seeing the word "Charlock" staring us out of countenance. In fact, already now there are signs of the invasion, for questions are being asked, and answers given, as to the best way of dealing with this plague. Anything is a plague that usurps the rightful place and nourishment of our crops. Weeds, of course, we expect to contend with; not only the annoying, tiresome Twitch, of which the tiniest scrap will live and grow, but all the host

of summer annuals, that cost the farmer infinite time and money to get rid of.

There are certain weeds peculiar to certain districts and also to certain seasons. On some lands "dodder" is a serious trouble, and spreading as it does with great rapidity it is very difficult to deal with. Beautiful as it may be in the eye of a poet to see a cornfield brightened by the Poppy, the farmer finds it anything but pleasing, and it remains an eyesore all the season, and is a standing joke with his fellow farmers. There is another colour that catches and holds the eye, and that is yellow. Poppies may be destroyed by timely harrowing, but the seed of the Charlock, being more or less oily, will remain buried, and then spring up to full life and activity when least expected. It is the spring corn that suffers from Charlock, and if we could only get the Charlock to start its growth before putting in the seed we could combat the enemy. The plants in an early stage are easily killed. As the plant usually appears simultaneously with the tender corn we are in a difficulty. A good harrowing is the remedy, but possibly the season is one when we fairly dare not harrow. Spring corn will not stand the knocking about that Wheat will.

Of course the old-fashioned plan was to pull out the Charlock in the flowering stage. That was most effectual, but also most costly. We cannot get the labour now, nor can we find the money to pay for that labour. An old hand will bear in mind a field that is subject to this pest, and will contrive so to crop it as to give the hoes every chance; but that often throws the whole course of the farmer out.

"Spraying" is not altogether a new idea. We have seen it used to combat disease in Vines, disease in Potatoes; the Hop gardens of Kent have long been familiar with different "sprays," and it was only this summer we saw an energetic parson who was fighting aphids and other like cattle that infested his fruit trees with a hose and charming preparation, which reached the under and upper side of every leaf. We do not want to "spray" insects; we want to "spray" plant life, and we want something to kill that plant life without injuring the legitimate crop. We have not arrived at this all at once; we could find plenty of Charlock destroyers, but they also proved destructive to other growths. We wanted something fairly simple and fairly cheap, for it was not on flower beds we experimentalised; it is a case of acres and acres.

Our various agricultural colleges took the thing up, and, by patient trials and careful observations, have arrived at some very definite knowledge. We are under obligations to the Editor of the last number of Royal Agricultural Society's Journal for a summary of trials and results. These experiments took in most of the counties of England. In Northumberland, and adjacent counties we find seventeen farms on which trial was made of the new destructor. Essex, Yorks, Cambs, Hunts, Northants, Suffolk, Sussex, Herts, Kent, Cheshire, Lincoln, and 200 other experiments made over the kingdom generally. There appear to be two chemicals equally destructive to Charlock and equally innoxious to other plant life. These two substances are sulphate of iron and sulphate of copper.

The copper is the easier and pleasanter to handle, and will therefore be more generally used, as double the quantity of sulphate of iron is necessary. The strength of the mixture appears to be 4 lbs. of sulphate of copper in 10 gallons of water, and the quantity per acre is estimated at 40 gallons. More has been used, and less, but it appears fairly certain that a larger quantity of greater strength is unnecessary, and that a smaller quantity weaker is not sufficient to kill the weed unless in quite the earliest stage. Some recommend two dressings of the weaker solution, but if the Charlock be taken at the proper time one dressing of 40 gallons of 4 per cent. sulphate of copper should be enough. In very few cases have the experiments proved total failures, and then possibly there is something left untold, the weather, strength of growth, or some other particular equally important. The weather is a great factor in the case. Sometimes it is that Charlock gets such a start because it is simply impossible to get on the land. The day for the operation must be

most carefully chosen. There must be absolutely no wind. A shower coming on say four to five hours after spraying will nullify all desired effects. The plant will not have had time to absorb the poison. A dewy morning is the best time, but the dewy morning must not be followed by too hot a day. Fortunately at that season of the year, when spraying should be in full force, the days are not particularly sultry.

The sulphate of copper should be mixed if possible with soft water in a wooden bucket—keep clear of zinc or iron pails. The knapsack sprayer will answer for small plots, but where the area runs into acres, Strawson's cart sprayer will be found necessary. Why this solution is fatal to Charlock has yet to be discovered. The following crops have been sprayed with the above results. Wheat, Oats, Barley uninjured; young Peas, not permanently injured; Peas in bloom, uninjured; Cabbages, uninjured; Turnips, killed almost as quickly as Charlock; Mangolds, not permanently injured; young Clover in corn, absolutely uninjured; Beans, not permanently injured; Tares, uninjured. We read of crops looking better and healthier after being sprayed for Charlock; no doubt this is because the legitimate crop, is getting more air and space, which is only reasonable.

To some of our readers 40 gallons per acre seems a large allowance but remember every leaf must be wetted. The estimated cost per acre will be about 4s. Mr. Homsley (Laxton Park) compares this favourably with hand pulling, which would come to about 30s. or 35s. per acre. We shall watch with great interest for all reports of spraying during the coming season. No doubt this new method of weed extermination will find (as it should) many advocates. We think at any rate it may prove a way out of a great difficulty. A clean crop should be a better crop, and we think we should more than see our money back at harvest time.

WORK ON THE HOME FARM.

Since the great snowstorm we have had rain almost every day and night; the snow has just disappeared, but the rain is still in evidence in the shape of flood water. Rivers are fuller now than ever; everywhere water meets the eye, and we fear the worst is not over.

Spring sowing is as it stood a week ago. If a favourable change were to come over the weather it would take a fortnight's sun and wind to make even light land fit to sow with Barley. A wonderful transformation must be seen if much of the Barley crop is to be sown before the equinox. We want March winds, and hope that Tennyson's "Raging Moon of Daffodil" may act up to its reputation. March dust is at a premium just now.

There is more work for men than for horses. The manure is all led out, and it is quite out of the question to attempt to go on the land. Delivering corn, bringing in cake and coals are hardly sufficient to keep the animals in exercise, meanwhile work is getting into arrears.

There is plenty of hedging and fencing for the men. Grips have to be cut to let off surface water from low places, and ditches must be kept clear. Field corners may be dug and forked over, whilst all odds and ends of scrapings, turf, and twitch rubbish may be carted into a heap, to be left to decay. Amongst this may be mixed Potato tops that have been used to protect the pies, and any straw from the pies not worth taking into the foldyards. February has seen the English root crop practically finished. We wonder whether such a thing has occurred before within living memory.

We have just come across a ram breeder who is sending gimmer hogs to market in their wool for slaughtering. Nothing but dire necessity would induce him to do such a thing. Grass is growing where there are no mouths to prevent it.

Good fortune smiles upon the lambing pen; the mortality amongst ewes is very small, and lambs are healthy. The fall of lambs is good, and the poorness of the Clover plant will be severely felt when the bulk of the pairs are put upon the seeds. There will certainly be no Mangold left to eke out the poor pasture. We wonder what effect the failure of the Turnips will have on this year's sheep number when the agricultural returns are published.

Eggs keep up in price, although the supply is now materially increasing. The weather has been bad for young chickens. There is nothing suits them like sunshine, of which the supply has not been large of late. Young chicks must not be stinted of warmth.

SPECIAL NOTICE.

SEEDS

IF YOU WANT

REALLY GOOD SEEDS,

At MODERATE PRICES, Apply to

Mr. ROBERT SYDENHAM

BRISTOL ROAD, BIRMINGHAM.

No One will Serve you Better.

MR. ROBERT SYDENHAM'S LISTS

Are acknowledged by all to be the Best, Cheapest, and Most Reliable ever published. They contain only the

Best Vegetables, Flowers, and Bulbs Worth Growing.

Being the selections of the Largest Seed Growers, Market Gardeners, and the most celebrated Professional Gardeners, and Amateurs in the Kingdom. They also contain very useful Cultural Instructions.

Liberal Prizes and Three Fifteen Guinea Cups to be Competed for in 1900.

The Splendid Vegetables exhibited for these prizes last year at Shrewsbury, London, Birmingham, Plymouth, &c., were acknowledged by all to be as good as any ever seen.

'SWEET PEAS A SPECIALITY,

At a Half to a Third Usual Prices.

NOTHING GIVES SO MUCH CUT BLOOM at so small a cost or so little trouble. To get best results SOW NOW, as directions sent with each Collection.

SPECIAL VERY CHEAP OFFER.

COLLECTION No. 1.—10 Very Good Varieties.

50 Seeds of each in separate packets, 1/3.

Emily Henderson, white; Mrs. Eckford, primrose; Royal Rose, rosy-pink; Lady Penzance, bright pale rose; Her Majesty, rosy-crimson; Firefly, intense cardinal; Emily Eckford, bright pale blue; Countess of Radnor, pale heliotrope; Captivation, rosy-purple; Triumph, salmon and blush.

COLLECTION No. 2.—10 Very Choice Varieties.

50 Seeds of each in separate packets, 1/9.

Blanche Burpee, finest white; Queen Victoria, pale yellow; Venus, pale buff, flushed pink; Lovely, rich coral pink; Oriental, bright rose; Colonist, deep lilac-rose; Mars, rich dark fiery red; New Countess, fine pale lavender; Prince Edward of York, salmon and rose; Stanley, dark bronzy-maroon, the best dark Sweet Pea.

SPECIAL PRICE FOR THE TWO COLLECTIONS, 2/6, POST FREE, WITH A PACKET EACH OF WHITE AND PINK CUPID (50 SEEDS), FREE OF CHARGE.

COLLECTION No. 3.—10 Newest Varieties.

50 Seeds of each in separate packets, 3/-.

Sadie Burpee, new white; Modesty, blush pink; Prima Donna, large pink; Lady Mary Currie, orange-rose; Prince of Wales, deep rose; Salopian, deep mulberry-red; Lottie Hutchins, buff, flushed pink; Gorgous, orange and pink; Lady Grisel Hamilton, best pale lavender; Navy Blue, deep violet-blue.

Special Price for the Three Collections, 5/-. With a packet of Pink and White Cupid, and four striped varieties (50 seeds of each), FREE OF CHARGE.

THE BEST SEVEN TOMATOES

In cultivation; often sold under other names to get fancy prices. Each packet contains about 200 seeds. Perfection, 3d., a special good strain; Polegate, best for exhibition, 6d.; Ham Green Favourite, 3d.; Frogmore Selected, raised by the Queen's Gardener, 3d.; Challenger, 3d.; Golden Perfection, 3d.; EARLY OPEN AIR, the best for outdoor work, 3d.

Special Price for the Collection, 1/6, post free.

THE FOUR BEST CUCUMBERS.

Each Packet contains 10 Seeds.

Lockie's Perfection, Rollison's Selected Telegraph, Covent Garden Favourite, and Marvel, 6d. each; postage 1d. each extra; or the Collection, 1/9, post free.

FULL LIST POST FREE ON APPLICATION.

Gardening in 1900.

CONCISE yet comprehensive and time-honoured definition of a garden, generally accepted, is that of a piece of ground appropriated to the cultivation of herbs, fruits, vegetables, and flowers; a rich, well-managed plot, a delightful spot or appurtenance of the home. The production of all the varied plants and flowers required, with the several crops of vegetables and fruit in the best condition, at the time they are wanted, also the attractive keeping of the home surroundings, is the work of the gardener. The prosecution of all the work that is necessary for accomplishing the end in view is gardening.

What an interesting, diversified, intellectual calling it is. How delightful, too, when all runs smoothly; when everything can be kept neat, trim, and orderly; when there are no impediments to the healthy progress of cherished plants; no lack of the coveted and admired flowers in their seasons; no break in the successional and rotational supply of vegetables; no accidents to prevent bountiful yields of fruit, hardy and exotic, outdoors and under glass. Then, indeed, is the occupation a happy one—health giving, mind inspiring, and exhilarating. It affords a rich reward to the devoted and successful amateur, and enjoyable addition to the not overwhelming emoluments of the thoughtful and industrious professional.

That is representative of the bright side of gardening, and there is not much wonder that, when seen at its best under most favourable conditions, it should exert an attractive force on those who wish to spend their lives amidst pleasant surroundings. Thus it is that amateurs in different grades are in ever increasing numbers becoming interested in the cultivation of various plants which appeal to their taste, as well as of the more substantial products that afford food of the most toothsome and appetising character.

That changes have occurred in the world of gardening during recent years is only the natural result of changing circumstances and varying fashions. We may regret the falling of some

great gardens of the past from their high estate, and the events that contributed to the limitation of the resources by which they were so splendidly maintained. These are misfortunes in which many more than their owners are compelled to share, but the increase of wealth by the mercantile community has been the means of bringing into existence other gardens of different grades, and not a few of them of considerable extent, while thousands more of moderate area, yet highly cherished and liberally supported, have been established during the present generation.

Broadly speaking, it may be safely said that at no period were there so many genuine garden lovers as at the present time, and certainly there were never so many persons engaged in the pursuit of gardening in its diverse aspects and allied industries as is the case now. These remarks obviously have reference to the conduct of nurseries, seed establishments, and market growing areas, as well as private gardens, also to the production of necessities connected therewith. When all these sections are taken into account, as they must be in an estimate of the public taste and requirements, some conception may be formed of the magnitude of the horticultural interest and industry in this country in 1900.

Perhaps in no other way is this more clearly shown than in the current literature bearing on the subject. Every class and section of garden lovers is provided for, from the cottager, artisan, and city clerk—whose few square yards in the suburbs is to him an earthly paradise—to the learned scientific cultivator and the professional gardener and advanced practical amateur. The wants of all are met; simple fare for the tyros with their odd shillings to spend, more intellectual repasts for the savants, substantial provision for the requirements of the wealthier section of the community, and guidance for those intelligent workers with high aims, who are laudably seeking to distinguish themselves in the art that so many adorn. Then, in addition, what can be said of the remarkable abundance and splendid quality of the trade literature connected with gardening? In one word of simple truth, it can be said that it cannot be equalled by that of any country in the world.

All this goes to prove that gardening as a pursuit of pleasure, with its necessary correlative commercial ramifications, is deeply rooted, and becoming more so yearly, in the affections of the people, from the most affluent to the well-to-do; also by the masses, who find agreeable relaxation in it from their daily labour of various kinds, while a greater number of busy workers find the means of livelihood within its sphere of influence than was ever known before. It is even said that the demand for skilled, steady, industrious young men is greater than the supply. This is somewhat of a novelty, and not, perhaps, to be entirely regretted. The vacuum, if such there be, is certain to be filled, and, it is earnestly to be hoped, by bright intelligent men, who are as well educated as they can be by their own exertions, and at the same time hearty and willing workers. Science is good, and examinations are good, but for young gardeners to get on in the world they must, as the Superintendent of the Chiswick Gardens has officially recorded, be also, and especially, *workers*.

That gardening has its checks in the ordinary routine is proverbial. This is a necessity of the case since it is to a large extent governed by ever varying natural influences beyond human control. It is also beset by obstacles of various kinds, with enemies visible and invisible in many forms; but all this and these give zest to the earnest man, affording stimulus to his thought and vigour to his action in efforts to prevent or overcome them, and the more stubborn the difficulties encountered the greater the triumph of success.

Episodes of a general nature are, moreover, always liable to occur to divert attention from our great pursuit of peace, and to draw some of its votaries beyond its influence. Even some of our most valorous soldiers are lovers of gardens; this has always been so, even though they be as wide as the poles asunder in their views on other matters. It is said of Charles I. that only a few days before his trial he ordered seeds of Spanish Melons to be "planted in his garden at Wimbledon," while his successor to that garden, the republican General Lambert, one of the victors at Marston Moor, is said to have been "as fond as the king of his gardens, and possessing the finest Tulips and Gilli-

flowers that could be had for love or money," and also that when the old warrior was banished for life to "the Isle of Guernsey, he there lived for upwards of thirty years amusing his leisure with horticulture." Thus men of the most diverse views generally may be and happily are, united in their love of gardening and pursue it in peaceful friendly rivalry.

Gardeners—those who derive the means of livelihood from it—love it, too, for its own sake. An observant clergyman has written, "Gardeners, though often hardworked, and even weighted with families, perhaps, yet delight in their work and its surroundings. Who besides a gardener reads so much about his business? Tradesmen, as a rule, do not spend their evenings reading about their trades, nor do grooms and gamekeepers about their callings; but a gardener reads his books on subjects of his craft, also the *Journal of Horticulture*, from the pleasure it gives him, as well as because of its help in his calling." It is this love—this devotion, plus knowledge acquired, and resolute action in striving for supremacy, that have largely contributed to make British gardening what it is in 1900. Long may it flourish to exert its wholesome influence on the nation's life.—MENTOR.

The Awakening.

HARSH were the winds and cold the showers that ushered in the month of March; the face of Nature was sombre awaiting the revivifying effect of a softer air and brighter sun. But in a day—almost in a moment—the aspect changed and the more genial conditions were followed by the awakening of plant life from its winter sleep. The hedges bristle with the tender green of the bursting buds, the Almond trees expand their beautiful flowers, the yellow Crocus open wide their cups to the mid-day sun, and the Snowdrop's bells hang in chastest beauty; everything points to the advent of spring, with its many and varied charms. The winter has not, perhaps, been typical, frosts have not been frequent and severe, snow has not come to spread its mantle of purity over the land to any great extent, but the awakening of the plants is none the less welcome or appreciated.

On every hand we can now see that touch of Nature of which poets have sung and in whose praise painters have wielded an inspired brush. We may see this and more. For is there not in the present abundance a promise for the summer and for the harvest? True it is too soon yet for one to hazard a prophecy of what the harvest time will bring forth. We may say, the probabilities are that we shall—have frosts and biting winds to nip the bud and the flower within its delicate casing, but the promise of spring is great, and "hope springs eternal in the human breast." Each season brings to every one of us who is engaged in the oldest art some reverses; each spring we think we can see the bounteous recompense for labour done; and each year some promises remain unfulfilled. Does the gardener lose heart and remain unresponsive to the witchery of spring? Never; no matter how he may have been beset by trials and troubles in the years that have gone he still presses onward and pictures in his mind the plant in all the glorious beauty of its flowers and the tree laden with its luscious burden. The fountain of hope is stronger in none than in the gardener, who tends with loving hand the plants he grows so well.

No months are more fertile of uncertainties in the garden than are March and April—the awakening and the anticipation. From day to day, as the buds enlarge to expansion, we look and hope for fine weather, but can never be sure of what the next twelve hours may have in store for us. Truly gardening is full of uncertainties. The cultivator must ever be on the alert to protect his developing crops from the visitation of a sudden frost, and many are the expedients that have been resorted to in pressing emergencies. Everything, apparently, has been requisitioned for one purpose or another, and if the articles employed have not always been ornamental, let us hope they have proved their value by their usefulness. Certain it is that the man who *acts* is the one who scores in gardening, and he who contents himself with *hoping* the frost will do no harm oftentimes finds himself minus a crop of flowers, or fruit, or vegetables. Every one of us no doubt can recall at least one disaster in our career that might have been averted by prompt action, and probably there are few who have not had to take a turn on a bitter night in covering some cherished crop of Potatoes or flowers in the garden or fruit on the wall. But it has been all for the best, and the gardener becomes somewhat of a philosopher who may gamble a little but seldom fails to do the best he can when the moment for action arrives. Procrastination with a frost in the air at night is liable to prove a thief of other things besides time. We are all rejoicing in the awakening; let us all, then, do our best to make the time of realisation—harvest—a period for rejoicing too.—S. E.

NOTES & NOTICES

Recent Weather in London.—The weather in the metropolis has changed during the past few days. On Saturday the sun shone brilliantly, and the air was almost as balmy as a May morning. Sunday, too, was mild, but the sun scarcely struggled through the haze. There was a suspicion of frost on Monday morning, but the day was mild and fine. Tuesday morning was much colder, and there was a slight dampness in the wind. Wednesday was a typical spring day.

Weather in the North.—Frosty nights and bright days have been the rule for the past week; the 8th and 9th, however, being duller. No rain has fallen, and the frost has put the heavier lands into fine working condition; and the Bean crop has been got in. 6° of frost were registered on the 6th, 9° on the 7th, and 6° on Saturday. Sunday was a beautiful spring-like day; Monday duller, with a coldish wind from the west. A good deal of snow still lies on the hills.—B. D., *S. Perthshire*.

Dahlia Show at the Royal Aquarium.—An exhibition of Dahlias on much the lines of that held last year will take place at the Royal Aquarium on September 18th and two following days. A sum of nearly £30 is offered in prizes—a portion of which has been subscribed by the directors of the Royal Aquarium, and the remainder by private subscription. Two main objects are sought by the establishment of this show—one is to provide an exhibition of Dahlias in central London, the other to afford a convenient opportunity for a further exhibition of seedling Dahlias. Schedules of prizes can be obtained of the superintendent, Mr. Richard Dean, 42, Ranelagh Road, Ealing, W.

After the Siege.—The following prices were realised at an auction in Ladysmith on the 21st of February: 14 lbs. of oatmeal, £2 19s. 6d.; 1 lb. of fat beef, 11s.; 1 lb. tin of coffee, 17s.; eggs, £2 8s. per dozen; a fowl, 18s.; four small cucumbers, 15s.; green mealies, 3s. 8d. each; a small quantity of grapes, £1 5s.; a plate of tomatoes, 18s.; one marrow, £1 8s.; a plate of potatoes, 19s.; two small bunches of carrots, 9s.; a glass of jelly, 18s.; 1 lb. bottle of jam, £1 11s.; 1 lb. tin of marmalade, 1 guinea; a dozen matches, 13s. 6d.; a packet of cigarettes, £1 5s.; fifty cigars, £9 5s.; a quarter-pound cake of tobacco, £2 5s.; half a pound of tobacco, £3 5s. Such figures as these ought to satisfy the most rapacious growers.

Death of Mr. E. J. Lowe.—By the demise on Saturday last, at Shirenewton Hall, Chepstow, of Mr. E. J. Lowe, F.R.S., horticulture generally, and Fern growers in particular, lost one of their keenest supporters. His knowledge of exotic and native Ferns was profound, and in his collection of these plants he found the utmost pleasure. Mr. Lowe was a founder of the Meteorological Society, and his meteorological writings and other labours have a permanent value. He was equally distinguished as a naturalist, and an authority on mollusca as well as Ferns. He was also an inventor. Mr. Lowe was a Fellow of the Royal and many other learned societies. For the greater part of his life he was closely associated, officially and otherwise, with the county of Nottingham. The deceased was seventy-five years of age.

Death of Mr. G. J. Symons, F.R.S.—Many of our readers who have worked in association with Mr. Symons in registering the rainfall in various districts will learn with much regret of his death from paralysis on Saturday last at his residence, 32, Camden Square, N.W. The deceased gentleman was a devoted meteorologist, and his notes of observations appeared in the *Journal of Horticulture* for many years. Mr. Symons was a most diligent and careful worker, and the deserved subject of many marks of recognition. He was the recipient of the cross of Knight of the Legion of Honour from the President of the French Republic in 1891, and the Albert medal in 1897 from the Prince of Wales for services in recording the rainfall. Mr. Symons filled the offices of secretary and president of the Royal Meteorological Society, and had some 3000 coadjutors throughout the country who sent him the reports which enabled him for nearly forty years to publish an account of the rainfall in the British Isles. The deceased gentleman was sixty-two years of age.

Mr. W. J. Bean.—We are informed that Mr. William J. Bean, who has been arboretum foreman at the Royal Gardens, Kew, has been appointed assistant-ecurator for the arboretum. Mr. Bean thus becomes a member of the permanent staff of the gardens, and there is little likelihood of his valuable services passing to another establishment, either at home or abroad.

Royal Meteorological Society.—At the ordinary meeting of the society to be held at the Institution of Civil Engineers, Great George Street, Westminster, on Wednesday, the 21st instant, at 7.30 p.m., the following papers will be read:—"The Ether Sunshine Recorder," by W. H. Dines, B.A., F.R.Met. Soc.; "Remarks on the Weather Conditions of the Steamship Track between Fiji and Hawaii," by Capt. M. W. C. Hepworth, F.R.Met.Soc.; "Comparison by Means of Dots," by Alexander B. MacDowall, M.A., F.R.Met.Soc.

Currants as a Food.—Fruit dealers say that London consumes more and more dried currants every year. Recent heavy importations of the fruit certainly tend to confirm the statement. A few days ago one boat alone—the steamship "Benmore"—unloaded at the docks 23,141 quarter-cases and 625 half-cases from Patras, and 5502 quarter-cases and 1376 half-cases from Zante. The quarter-cases are becoming very popular among the small consumers. It seems likely that, as in the United States, the currants will also soon be sold in 1 lb. boxes.

Tomato Disease in Australia.—Several Tomato growers about Sydney, N.S.W., have been puzzled to notice fine healthy plants suddenly collapsing and dying as if struck by a plague. The peculiar disease has recently, says a contemporary, appeared on a large scale in the Gosford district. Specimens sent to the Agricultural Department have been examined, and found to be infested with the "sleeping disease of Tomato, a fungoid known as *Fusarium lycopersici*." The entomologist states that this is a very common disease in England, where it causes great losses to market gardeners growing Tomatoes. It is likely to spread, as if the plants are attacked when in full fruit, as is often the case, the fruit may ripen, and appear, even under the microscope, to be perfectly sound, yet the seeds from such Tomatoes, if planted, will produce diseased plants.

Death of a Distinguished Scottish Gardener.—It is with deep regret that we have to record the decease of Mr. William Hugh Gorrie, late gardener to Sir W. Hozier, of Mauldslee Castle, Lanarkshire, on the 5th inst., aged sixty-five years, after a painful and protracted illness. Mr. Gorrie was well known throughout Scotland as one of our most successful gardeners. Such has been exemplified for many years past in the fine gardens of Mauldslee, where his skill and management have been so much in evidence. The deceased was associated with gardening from his childhood. Mr. Gorrie had capital training under his father, who was gardener at Polmaise, near Stirling, for many years. After making the best of his time as apprentice and journeyman he went as foreman to Luchie, in East Lothian, and was for some years foreman at Tynningham, under Mr. Lee. From there he went to Raith as head gardener to the late Colonel Ferguson, after whose death he went as gardener to Sir W. Hozier. Mr. Gorrie leaves a widow and family to mourn his loss.—M. TEMPLE, *Carron, N.B.*

A Novel Suit.—Some months ago a Mr. John Coleman of Williamsport, Pa., instituted legal proceedings against a Mr. D. E. Gorman, who owns greenhouses directly across the street from Coleman's residence. The plaintiff alleged that the glass sides and roof of the greenhouses are constructed at such angles that at all times when the sun is shining the beams are reflected so that they strike Coleman's plot and the dwelling house with such brilliancy as to render the rooms in the front part of the house and the porch uninhabitable, useless, and unfit for occupation and dangerous to the health of the occupants of the dwelling. Mr. Coleman therefore asked for relief as follows:—First that the greenhouses be declared a nuisance; second, that the defendant be compelled to remove the same; and third, that he be restrained hereafter from maintaining buildings constructed of glass on his premises. The court, after hearing the evidence in the case, gave Mr. Gorman until May 1st, 1900, in which to remedy the matter and do away with the reflection, and stated that in the event of his failure to do this, he would grant the injunction as asked. Needless to say, Mr. Gorman feels that this is a very unjust decision, but he has not taken an appeal. If this is sound law there may be a good many reflections which will land greenhouse owners in court.—("American Florist.")

United Horticultural Benefit Society.—The annual meeting of this association was held at the Caledonian Hotel, Adelphi, on Monday, March 12th, Mr. Richard Dean, V.M.H., occupying the chair in the absence through indisposition of Mr. S. T. Wright. There was a fairly large attendance of members, whose expressions relative to the committee of management proved that the affairs of the society were most satisfactory and in perfectly capable hands. There can be no doubt that this is essentially a benefit and provident society that tends in every way to benefit members of the craft who are also members of the institution. Each of the several funds shows a substantial balance in hand, and the total amount of invested capital now amounts to nearly £16,000. It was mentioned as indicative of the admirable management that the dividends on the several investments exceeded by upwards of £20 the whole of the expenses for the year. We shall give fuller detail in our next issue.

Blyth Gardeners' Society.—Mr. Mallender, Hodsock Priory, recently gave an excellent lecture on "Daffodils." The room was well filled by an appreciative audience. The lecturer dwelt chiefly on the history of the flower, going back 3000 or 4000 years. He mentioned the names of several ancient and modern poets who have sung the praises of its beauty. The Daffodil is found wild in Great Britain, also in Southern and Central Europe, on the shores of the Mediterranean, China, and Japan. There are about 400 varieties named, the prices varying from one halfpenny to 12 guineas each, and some are quoted even higher than that. Up to a very few years ago we were dependent on the Dutch for our supply of Daffodils, and even up to the present day the Dutch send enormous quantities to meet our requirements. There are, however, several growers who have taken up the cultivation of the Daffodil at home, and Mr. Mallender drew special attention to the soil in and around Blyth as being in every way suitable to the cultivation of the favourite flower. He fully described the modes of cultivation. A hearty vote of thanks was proposed to the lecturer by the Rev. C. E. Scott Moncrieff, and carried.

Reading Gardeners' Society.—The large attendance of members present at the fortnightly meeting of the Reading and District Gardeners' Mutual Improvement Association on Monday last testified to the increased interest which is now being taken in hardy flowers. The subject for the evening was "The Formation and Arrangement of a Hardy Border with a List of Plants Suitable for Same," by Mr. D. Harris, gardener to Col. Jekyll, Munsted House, Godalming, and it is needless to say that the paper was of a very practical character. The lecturer described the best sites, formation of same, soil, suitable plants and their arrangement, time of planting, and many other essential points. A large number of questions were asked, and an interesting discussion followed. A feature of the evening was two splendid floral exhibits by Mr. F. Lever, The Gardens, Hillside, Reading, and Mr. W. Townsend, The Gardens, Sandhurst Lodge, the former staging *Azalea indica alba*, *A. Deutsche Pearl* (grown from cuttings), *Doronicum caucasicum* (grown in pots), and a splendid flowered *Dendrobium nobile*; whilst the latter staged a beautiful group of *Begonia Gloire de Sceaux*.

Sandy Horticultu Society.—The recent annual meeting, under the presidency of Mr. J. F. Love, was well attended. Mr. Sills, assistant secretary, read a report and balance-sheet, which were most gratifying as showing marked success and all-round advance. The income is now over £1000, and whereas at the first show in 1869 only £64 13s. 9d. was paid in prizes, last year the total was £439 15s.; in the former year the gate-money was £27 19s. 3d., and last year it went up to £416 11s. 4d. £100 was added to the deposit account in the bank, making a total of £175 11s. 2d.; there was £3 2s. 4d. in the treasurer's hands, and subscriptions in arrear, thought to be good, amounted to £5 10s., so that the total assets of the show are now £184 3s. 6d. The chairman considered this a most satisfactory position, and the reports and accounts were unanimously adopted. It was agreed to ask Mr. R. O. Fordham of Broom to be president for this year, and Major Shuttleworth's name was added to the president's list. A hearty vote of thanks was accorded to Mr. Gerald D. Smith for acting as president last year. The chairman, in proposing a cordial vote of thanks to Sir Robert Edgecumbe for the use of his park for the show, said that was the essential item for the success of the show; for during its career of thirty years it was only out of Sandye Place once, and that very nearly killed it. Hearty thanks were also accorded to the rector for opening his grounds to the donors of special prizes, and to the committee and officials.

Metropolitan Public Gardens.—At the last monthly meeting of the Metropolitan Public Gardens Association a vote of condolence was passed with the family of Mr. J. T. Bedford, who died at an advanced age. He had been vice-chairman of the organisation from its inception. It was reported that the purchase of Dollis Hill Estate as a public park had been completed by the Willesden District Council, and that another scheme for the purchase of the Alexandra Park and Palace for public recreation had been revived with some prospect of success. It was stated that among other work of the association it was engaged in laying out St. Mary's Churchyard, Plaistow, and Christ Church Churchyard, Blackfriars, as public gardens, and would shortly begin the formation of a children's playground at Sumner Road, Camberwell.

Hessle Gardeners' Society.—A fortnightly meeting of the above society was held in the parish schoolroom on February 27th, Mr. Mason in the chair. A very interesting and suggestive paper on horticultural exhibits and point judging was read by Mr. J. P. Leadbetter, gardener to A. Wilson, Esq., Tranby Croft Gardens, Hull. The essayist, in a few well chosen remarks, referred to the necessity of a method of point judging, which should be established on a system that would be applicable to groups, specimen plants, cut flowers, and vegetables much in the same way as is occasionally done with fruits. He also stated very definitely that the true value of every individual point should be found in the exhibit. An interesting discussion ensued, which brought an enjoyable evening to a close. The committee is doing its utmost to establish a summer show in connection with this society. The efforts have so far been favoured with the generous support of the public. In addition to receiving the support of the president, A. Wilson, Esq., other influential gentlemen have promised their patronage.—J. F. D., York.

Bristol Gardeners' Association.—The usual fortnightly meeting of the Society was held at St. John's Parish Room, Redland, on Thursday, 8th inst. A large attendance was presided over by Mr. Chas. Lock. Mr. R. Stewart, Sneyd Park, provided the paper, which was on the subject of "Peaches and Nectarines." He disclaimed at the outset any intention of dealing with the culture of the fruits in the open air, and confined his remarks to orchard house culture. Handling the subject in a masterly way, he described the structure he thought most suitable, the method of preparing the borders for planting, the soil best suited to the plants, and the time and manner of planting. He also gave a good deal of information respecting the pruning and training of trees, root-pruning, disbudding, and thinning of fruit, also urging care in watering, that the trees may never get quite dry on the one hand or very wet on the other. Mr. Stewart concluded an able paper by enumerating the varieties he thought most useful and the many pests to which Peaches were liable. A good discussion followed, and Mr. Stewart was accorded a hearty vote of thanks on the motion of the chairman. Prizes for three Hyacinths were awarded, Mr. Price first, Mr. Pidgeon second. Certificate of merit went to Messrs. McCulloch and Quick (each for a fine specimen of *Cœlogyne cristata*), Mr. White (*Cymbidium eburneum*), Mr. Cutler (*Dendrobium Wardianum*), Mr. Price (*Dendrobium nobile Cooksoni*), and Mr. Quick (*Dendrobium nobile*).

A week almost without rain, dull, and sunless, with cold north-easterly winds.

Zygopetalum Balli.

THE number of new *Zygopetalums* that find their way to the Drill Hall or, for the matter of that, to any exhibition, is comparatively limited, and one is, perhaps, as a consequence received with the greater pleasure. On Tuesday, February 27th, *Z. Balli* (fig. 55) was shown before the Orchid Committee of the Royal Horticultural Society, and received the award of merit. The flower is decidedly handsome, and distinct from all other members of the family. The sepals are rosy carmine with a white base and margins; the petals are of a similar shade, but the colour is not in one mass, but is divided into spots at the tips. The central portion of the lip is deep crimson, and the front lobe is pure white. The exhibitor was G. S. Ball, Esq., Wilmslow.

Cypripedium Ashworthæ.

The hybrid *Cypripedium* named *Ashworthæ* (fig. 56) was first exhibited by E. Ashworth, Esq., Wilmslow, Cheshire, in the autumn of 1893, when it was honoured by the Orchid Committee of the Royal Horticultural Society with an award of merit. It was said to be the result of a cross between *C. Lceanum superbum* and *C. selligerum majus*, and the flower is of an attractive appearance. The dorsal sepal is very fine, chiefly white with a green base spotted purple. The petals and lip are of a rich bronzy purple shade. This information will no doubt meet Mr. R. Browne's requirements.

Odontoglossum lyroglossum.

Botanists find little difference between this and *O. luteo-purpureum*, and possibly they are in the right of it from their point of view. All the same it is easy enough to pick the plant out, and it is quite distinct from all other varieties of this very variable section. The petals come almost at a right angle with the dorsal sepal, and the lip is usually a

FIG. 55.—*ZYGOPETALUM BALLI*

little rolled. The brown spots on the yellow ground are clear and well defined, and altogether it is a variety well worthy of care and attention.

Orchids for Cutting

Those who cultivate Orchids simply for the sake of cut flowers are at a great advantage culturally to others who grow for a lengthened display in the houses. This, for the obvious reason that many plants of not over-strong habit have yet vigour enough to produce and perfect blossoms, but to carry these over a few weeks would prove too great a strain. Their increasing popularity for this purpose is a better argument

in their favour than any encomium I could pass upon them, and a brief list of the best of those to keep up a display throughout the year will be more serviceable.

Of the highest importance in this connection is the beautiful *labiata* section of *Cattleya*. Their culture is so simple that even a tyro in Orchid growing will be able to keep them in health, and if he does this they are sure to flower profusely. The only exception to this rule is *C. gigas*, which does not flower freely in all collections, but is not shy if properly treated. Besides this and *C. labiata autumnalis* we have *C. Dowiana* and its better known variety *aurea*, *C. Eldorado*, *C. Gaskelliana*, *C. Luddemanniana*, *C. Mendeli*, *C. Mossiæ*, *C. Percivaliana*, *C. Trianae*, and *C. Warneri*. All these are variable, and given a good selection of each there will be little difficulty in keeping up a display of flowers throughout the year.

FIG. 56.—*CYPRIPEDIUM ASHWORTHÆ*.

Cypripediums of course cannot be left out of a list of this kind, but so numerous are they that nothing like a representative collection can be grown in most places. Many of the hybrids raised from the older free-blooming kinds are excellent for the purpose indicated, and these old ones themselves ought not to be forgotten. Any of the hybrids that have blood of *C. insigne*, *C. barbatum*, or *C. villosum* are good, and the newer *C. Charlesworthi* is excellent. All may be used again and again for decoration if the water is frequently changed, while the culture is remarkably simple.

Early in the year the well-known *Coelogyne cristata* is capital for cutting, the pretty white flowers on light elegant sprays coming in usefully for every purpose for which cut flowers are likely to be needed. *Dendrobiums* are a host in themselves, whether it is the spring-flowered species with small fascicles of showy flowers like *D. nobile*, *D. Wardianum*, and a number of others, or the lovely autumn and winter-flowering species such as *D. phalaenopsis*, *D. bigibbum*, and *D. Johnsoni* (*D. Macfarlanei*).

Lælias such as *L. purpurata* and the Mexican species and varieties, almost the whole of the large *Odontoglossum* family, and the equally beautiful *Oncidium*; the showy *Masdevallia*, *Sophranitis*, *Epidendrum vitellinum*, and *Lælias harpophylla* and *cinnabarina*, all with bright orange or scarlet blossoms, cannot be left out, and there are many others that might be named.

Into the culture of these it is not necessary to go now, but a few of the leading points should be noted whether the plants are to be

grown in the Orchid house proper or in a structure devoted to stove or greenhouse plants or Ferns. Cleanliness of the plants is of first importance, and in all cases it is safer to keep them rather under than over-potted. Water liberally through the medium of the atmosphere, but do not overwater the roots. Use all composts of the very best description; it pays in the end even if the first cost is higher, as it is so much better for the plants and more lasting. Remember that it is always easy to retard a plant that seems likely to be too early, but it is impossible to force a cool house Orchid with any likelihood of success.—H. R. R.

London Gardens over Fifty Years.—No. 20.

TRAVELLING along the Uxbridge Road, after passing Bayswater and Notting Hill, we come to Shepherd's Bush, and the name makes us smile. The locality in 1900 does not help us to picture a shepherd sitting under a big bush or tree, having a rest, perhaps a read or smoke, his dog by his side, and his flock quietly grazing around. It seems a fancy, yet something like it was a fact not so very long ago. About this district of the suburbs there used to be extensive pasture lands, and it had its shepherds, even as Notting Hill could show its Nut copses, which suggested the idea that it took its name from them; but, more probably, authorities trace it to the old manor of Knotting-barnes. This was standing at the beginning of the century, being occupied as a farm; the public road to Kensal Green ran through the farmyard.

Along the meadows to the north cattle and sheep were numerous; though scarcely three miles from London, says one, you might have fancied yourself in a sequestered part of the country. Few sounds were to be heard except the tinkle of the sheep bell, or the songs of the lark, linnet, and nightingale. But fifty years ago people had discovered it was more profitable to grow vegetables than to have the land in grass, and some of it, too, began to be built over. Wormholt Scrubs, incorrectly called "Wormwood," is an outlying portion of the estate, still a somewhat wild tract of nearly 200 acres. Part has for a considerable period been devoted to State or military purposes; a smaller portion is, I believe, to be laid out as a garden by the London County Council.

Upon a plot of land at Notting Hill, which was parish property, and bore the name of Charecroft, there existed an old nursery which I can just remember. Its last occupier, I believe, was a Mr. Middlemist, and it then bore the title of "Cape Nursery." This was one amongst others so-called, at a time when South African plants were much sought after, and travellers wandered in quest of them through regions which now resound with the tumult of war. From what we read descriptive of home life in the districts colonised chiefly by the Dutch, it does not seem that the modern Boers have inherited the love of florists' flowers which was conspicuous amongst their ancestors in Holland, and, indeed, still exists there. But there never has been much about Notting Hill to interest gardeners, excepting, indeed, some of the squares, which have trees and shrubs judiciously arranged.

About 1850 many were desirous of getting a peep at the gardens of Campden Hill House; so much had been done there within the small space of 4 acres by the gardener to the Dowager Duchess of Bedford. As a matter of course, Holland House, on the Kensington side of the hill, has always had its horticultural memories. No longer can it boast the "deep seclusion," which so charmed Walter Scott. Part of the grounds has been cut off for the erection of villas; the residence, long associated with the Holland family, is now occupied by Lady Ilchester. Through many years the garden has been in the charge of Mr. C. Dixon.

Nothing beyond a passing mention can be made of this historic mansion and grounds, which some years ago served as subject for a splendidly illustrated volume. There are fine Elms and Limes, also a few good Cedars, but many trees and shrubs have suffered from the fogs of London, which often seem to settle thickly about the locality. The square used to make a show in summer with Oranges and other tender trees which were brought out of the houses at that season. In the large conservatory, which has a banqueting room attached, there has always been a choice assortment of plants; the Orchid house, 90 feet long, and the series of forcing-houses were indicative of wise selection and skilled management. Box was, and is, much in evidence—scattered trees of it, hedges, edgings; some of the latter are said to have been growing nearly a century. Several years ago it was the fashion, along the greater number of the flower beds, to have the plants all of a dwarf character, to preserve the outline. Now, however, modern styles are mostly followed. It would indeed astonish the eighteenth century worthies who wandered amid its shady walks to see the display of summer flowers at Holland House. The Dutch garden is a choice relic of the past, with its intricate pattern of beds, and walks occasionally too narrow to be trodden separate some of

these. Letters, animals, and scrolls come into the design, while angles exhibit balls of Box or Evergreen Oak. Many rare shrubs were planted by Charles Hamilton, of Pain's Hill, who may have been the planner of the circular rosery.

Old Oak Farm, lying north of the road to Acton, seems to have gone the way of most suburban farms. Oak hedges really did bound some of its fields, which are rather unusual near London. The name of Oaklands still remains attached to some residences. Evidently woods or copses of Oak were common hereabout, spurs thrown out from the great forest of Middlesex. Some assert, indeed, that Acton was originally "Oak-town." Willows and Poplars also flourish in this district, which was formerly crossed by various streamlets running towards the Thames. Even the Rose appears at one time to have been freely grown on a spot to the south of the Acton Road, for there was a nursery called Rose Gardens existing thirty years ago. Perhaps Acton itself has its Roses, for there is a Rose-mont Road there, in which is the nursery of Mr. Capper.

But this suburb has never been so notable as some are for its nurseries and market gardens. One firm of repute was that of Reeves, who formerly had offices in Notting Hill; they were large importers and growers of bulbs, Tulips especially, their grounds being at Acton. It is said they sent out in some years more than 150,000 Tulips alone, but the business has ceased to exist. Reeves' garden now forms part of Acton Park or recreation ground, towards the purchase of which £5000 was given by the Goldsmiths' Company. Laundries now occupy the site of the nursery once belonging to Mr. Puttick, and that of Mr. Day, in Acton Lane, towards Chiswick, also that of Mr. Jennings, Acton Green, while the orchards and gardens to be seen at South Acton twenty years ago have been cleared for the builders. Towards Gunnersbury there yet remain two or three small nurseries, and Mr. Morris still has, in Church Road, an establishment well known locally.

Probably in a short time the remaining market gardens on the Rothschild estate will disappear, and the few fields left about Strand-on-the-Green be covered with houses. To many living at the west of London this little suburb on the Thames is quite unknown. Gunnersbury Park may be considered secure from the builder; its Orchids were often talked of at a time when that group had few cultivators. Visitors have also sought it to see Kent's handiwork, who laid out the pleasure grounds in the reign of George II. Then its orangery was considered one of the best in Britain. It had besides a remarkable Tulip Tree, a very large Magnolia grandiflora, and two Tree Ferns (I forget the species) of exceptional size. The stoves and forcing houses have for almost a century had a high repute.

Amongst those who represent horticulture at Ealing, we are tempted to put first the name of Mr. R. Dean, V.M.H., of Ranelagh Road, though we cannot ascertain that his is the oldest of the nurseries in the district, which are not numerous. About twenty years ago somebody said Ranelagh Road was famous for Pansies, Polyanthes, Primulas, and choice Potatoes; but Mr. Dean certainly takes a range beyond that letter of the alphabet! He takes much interest in the Dahlia and the Chrysanthemum. Just now he is actively assisting the promotion of the Sweet Pea bicentenary.

Concerning the Sweet Pea, I note the fact as singular that Loudon, in his "Encyclopædia," simply gives it a place under the index, saying nothing about its culture or varieties, perhaps thinking it needless. But it has long been a popular flower with the Londoner, though now he frequently has higher aspirations, and seeks showier or costlier plants. In some places the Everlasting Pea is the favourite, because it flourishes and spreads from year to year. Strolling with a friend in a rather populous suburb he called my attention to a shop window which had a bill, "Pea sticks sold here." "Whatever can they want with Pea sticks hereabout?" said he, laughing. Then I explained that the folks of that district did not, of course, grow the edible Pea, but had a pride in getting rows of Sweet Peas along their back gardens. Mindful of the partiality of sparrows for the seeds they often took the trouble of sowing them in pots, keeping them indoors till the young plants could be transplanted.

The long-standing firm of Messrs. C. Lee & Son has still a branch at Ealing, but the extent of ground has been diminished of late. Ealing Dean used to draw visitors to the grounds of Mr. Smith, noted for his Cyclamens, of which he sent out above 10,000 some seasons. He had a large house devoted to Poinsettias, and Solanums were a specialty; he also had many thousands of Begonia weltoniensis, and various Cinerarias. Fuchsias, too, occupied an important place, having a large sale. This nursery has, I believe, ceased to exist, though a Mrs. Smith carries on a florists' business in Ealing Broadway. In Matlock Lane we find the nursery of Mr. Cannon; and that of Messrs. Hart Brothers is in the Grove. Ealing Park, well known forty or fifty years ago on account of its extensive collection of plants, which Mrs. Lawrence, the occupier, allowed the public to inspect once a week during the summer, has undergone changes since that time. Its extent has been reduced but the market gardens and orchards of the locality have yet resisted the builder.—J. R. S. C.

Seedsman's Guarantees.

To call a plain statement of fact "quibbles" is neither argument nor the best of taste, nor does the fact that "A. D." has only a limited knowledge of a subject render it incomprehensible, at least to others. His statement that 99 per cent. of the seeds supplied at the present date are good and true to description is perfectly correct; but we have it also on reliable authority that about the same proportion of the population of these islands are—well, not wise men. Any good seed firm would gladly guarantee their seeds if they could insure their being properly tested, but to guarantee the crop under all conditions of climate, or folly and incompetence on the part of the sower, is quite another matter. I could give enough instances bearing on this to fill the *Journal of Horticulture* were it worth while, but perhaps it would not serve any useful purpose. Those who wear the shoe generally know best where it pinches; and seedsman wisely prefer not to leave themselves entirely at the mercy of any person who may seek to cover his incompetence through legal proceedings.—CHAS. E. PEARSON.

Judges and Judging.

MANY times in the past has the subject of "Judges and Judging" been discussed in the *Journal of Horticulture*, though evidently, in the opinion of "An Inquisitor" (page 179), it has not been "thrashed out." Possibly it never will be to the satisfaction of everybody, but that is no reason why any ambiguities that may exist should go on without protest, or suggestions for improvement.

As to the question of "the same judges being employed year after year in the same classes at the same shows," may we not reasonably suppose that if, and when, such is the case, the continuation of their services is based on the fact of their having given satisfaction to the committees of the respective societies, as well as to the general body of exhibitors? If this is so, why should not such judges be re-chosen if it be the desire of the electors? If "An Inquisitor" were one of these judges in whom confidence is reposed because his competency and integrity had been fully tested, would he, in view of those facts, think it right to be superseded by, it might be an equally good adjudicator, but one who had still to prove himself so for the purposes desired at that particular show?

Is it not probable that no persons know so well as the secretaries of societies the measure in which the annually chosen adjudicators are trusted? The officials have protests to deal with and if these are many, and sustained, changes would be imperative; but if few or trivial, would not the officials be justified in relying in the main on men of proved capacity, or in other words, trusting to the bridge of proved soundness for bearing the strain to which it must be exposed?

If your correspondent had entered a protest against the judges who had, year after year, proved their fitness for dealing with particular classes being transferred to others for which they were less fit, would he not have been on firmer ground? Most people, on reflection, must surely be inclined to think so.

It may be urged that if the same judges always act at a particular show there can be no chance for younger men to share in the work of adjudication. That is quite true; but as a matter of fact changes are made at most of the shows he mentions, some gradually, others more generally. Personally, I think it advisable to bring in fresh and younger men to act with the "old stagers," but committees are often loth to make experiments, as they say, in that direction; still, in some way or other intelligent young men who have experience of shows and are acquainted with the cardinal properties of exhibits, seem to gradually and naturally come to the front as adjudicators.—AN EX-SECRETARY.

I WAS delighted to read the views of "An Inquisitor" on this subject on page 179, for they have arrived at a most opportune period—a time when most small societies are selecting their judges for the summer and autumn shows. It is a matter that has often occurred to my mind, but I have never thought of ventilating my views in the pages of the *Journal of Horticulture*. I quite agree with your correspondent that the same judges should not officiate year after year at the same show. As a judge I have attended and adjudicated at twelve successive exhibitions, and perhaps some of your readers have acted in the same capacity for twice that number of exhibitions.

My chief objections are that the judge, or judges, become well acquainted with the committee, the majority of whom are exhibitors; this gives rise to unpleasant remarks by some of the outside exhibitors,

doubtless without reason, but still the fact remains. Again, the same exhibitors stage at their show annually, and the judge, however much he may try to avoid it, soon recognises the style, yes, and even individual plants; and where the competition is keen and the prize of considerable value, it is sure to harass the judge more or less. I am also acquainted with a Chrysanthemum show where one exhibitor has staged in precisely the same spot for five years in succession to my knowledge, and as in this case it is a group of plants, I cannot fail to recognise it every year, as does my fellow judge, who has officiated for nine years. At the same time it is gratifying to know our decision has never been questioned. In this instance I suggested to the secretary that it would be wise to have a change of judges, but the committee scouted the idea, and I have no doubt this has occurred in dozens of other cases.

In my opinion the judges should not act at a show more than two years in succession—not that I think it interferes with their judgment, but it gives greater confidence to the exhibitors and does away with that petty carping that I am afraid is too prevalent at our shows, though it is now rare to hear much grumbling from the exhibitors; whatever they may think it is pleasing to find the majority keep their opinions to themselves, or express their views privately.—AN ESSEX JUDGE.

Apple Duke of Bedford.

FOR several years I have been seeking information about the origin of the above-named Apple, but up to the present I have failed to obtain any definite statement concerning its history; nor can I find a collection, either trade or private, which includes it.

In Dr. Hogg's fifth edition of the "Fruit Manual" it is described on page 64, and it is there said to be "a first-rate kitchen Apple, in fine condition at Christmas, and will keep till February," but nothing is said about its origin. I have all the editions of the "Fruit Manual" except the fourth, and the variety does not appear in the first, second, or third, so I take it to be a modern variety, as the third edition was issued in 1866 and the fifth in 1884. I shall be obliged if any correspondent could give some information about the variety, and if the late Dr. Hogg's manuscript is still in existence possibly the Editor may be able to find a clue.—R. LEWIS CASTLE.

[This Apple is not included in the fourth edition of the "Fruit Manual," and nothing relating to the history of the origin of the variety can be found amongst the MS. left by the late Dr. Hogg. Perhaps some of the experienced readers of the *Journal of Horticulture* can supply the information Mr. Castle desires.]

The Sweet Pea Bicentenary.

AT last one of our most charming garden flowers is to have its due. After years of almost absolute neglect a number of horticulturists have come together, and will endeavour, by the aid of an exhibition and a conference, to reduce order out of chaos—at least such is what I gather from a copy of the proposed scheme. I feel I must, in the pages of the *Journal of Horticulture*, congratulate the prime movers and wish them unqualified success. The names of those managing the affair are largely unfamiliar to me, but I recognise sufficient to assure me that this is not a trade move, but a loyal effort to increase the popularity of this beautiful plant amongst all classes of growers.

I have seen the displays of Sweet Peas that are brought together at Wolverhampton and Shrewsbury, and have often thought what a splendid spectacle would result from a show devoted solely to them. I am now hoping the weather will be propitious, and that the fates will permit me to be in London on July 20th, in which case I shall soon find my way to the Crystal Palace. I should like to see myself amongst the exhibitors, but am very doubtful if this wish will be realised, as I have not been successful enough to produce flowers good enough for staging so far. However, I must redouble my efforts this year, as I hope every Sweet Pea grower will do, so that I may, with good fortune, be enabled to support a movement with which I am so entirely in sympathy.

I have had a glance through the preliminary schedule, and find that there are several classes to which the smaller amateur can devote his attention. As a rule the classes scheduled for Sweet Peas are slightly beyond the growers here alluded to, but in this instance they have every consideration shown them. The prizes throughout are of exceptional generosity, and should be productive of the keenest competition. If the entries prove very numerous I venture to predict that the exhibition will be one of the most beautiful that has ever been held in the Crystal Palace, or for the matter of that, out of it either.

So far I have heard nothing very definite relative to the Conference, but presume it will take the form of three or four short papers and subsequent discussions. These should prove valuable, and I trust the Committee will see its way to print the papers and discussions verbatim in pamphlet form at a price of 3d. or 6d. The proposed classification of the varieties might also be advantageously embodied. There must be some record, and this seems to me the best means.—A. J. R.

Pentstemons from Seed.

IN a note on Pentstemons at page 184, it is stated that "March is rather late to sow seed to obtain plants to flower the same season." That is, however contrary to my experience, for I used to raise several plants yearly from seeds sown in a cold house early in March, getting in that way strong plants several inches in height, and planting out at the end of May. From these plants, which were simply dibbled out and if dry watered once or twice, I invariably obtained strong ones that bloomed freely through the autumn right up to November. I mention this because it is well that those who like Pentstemons, and either lose the old plants in the winter or do not care to keep them, may always have a fine show of bloom from plants raised as described in March for fully three months in the autumn. If some seeds be sown in a box or frame at the end of August strong young plants are ready to put out at the end of March, and these will bloom through June and July. We have now some fine strains of Pentstemons.—GROWER.

Pinching Fruit Trees.

A "LEARNER," who appears to know a good deal more about the Woturn experiments, as well as claiming acquaintance with the methods of many and extensive fruit growers, than "learners" know generally, confesses, on page 179, to being "staggered" by what I ventured to advance on the rationale of shoot-pinching on page 154. It is something to "stagger" such a widely experienced "Learner," and it could not have been done in the absence of impairment of his mental digestion. He tells us he has read "carefully" the article that was too much for him. Perhaps he read it too quickly; be that as it may, he has evidently not assimilated it. As a matter of fact, he has missed the point and so based an argument, or rather evolved a deduction, from a false hypothesis entirely of his own invention. This may be put to his credit, as it is not easy to be the real originator of anything in these days, in which so many try and fail. Says this Learner, "if it would pay to pinch a quarter of an acre it would pay to pinch a thousand acres" (of fruit trees). His proposition would have been as good had he started with a quarter of a tree as with that portion of an acre, for when he acquires the art of pinching, or finger-and-thumb pruning as it has been described, in its integrity, he will be able to have a quarter of a Peach tree bearing its crop of fruit from short stubby spurs and the other three-quarters from natural summer shoots in the usual way. As to which method would "pay" the better in view of the time involved in the operations, is another matter entirely.

So it was as clearly stated in my article bearing on the subject of pinching trees for a specific purpose and positions. A "Learner" is wholly wrong in his implication that I "advocated" systematic pinching as being more profitable than simpler methods of procedure. I did nothing of the kind. I suggested the contrary, as my critic really admits. Well may he be "staggered," such mental confusion as I happen to have extracted would be enough to stagger any man. I did not "advocate" a general principle to be followed in economic fruit production at all, but explained a method, by request, as applicable to the production of fruitful trees limited to small prescribed spaces in gardens.

When a "Learner" has learned much more in the school of experience he will find that trees are like men, varied in their habits and proclivities, and that all are not amenable under all circumstances and with differing objects in view to precisely the same treatment or training. Some are pliable and easily governed, others are more or less angular and known in nurseries as "awkward." Of course I mean trees, though the remark may, perhaps, apply to men, and some of these—so do men vary—might even be disposed to assume that the thoughts of my peculiar critic were not exclusively devoted to fruit trees, but also in a gentle way to "pinching."—A LINCOLNSHIRE GARDENER.

Cyclamen Culture.

HAVING noticed several articles in the pages of the *Journal of Horticulture* dealing with the culture of Cyclamens, I thought I would give my method of cultivation, as it differs somewhat from any I have seen described.

I usually sow the principal stock of seeds during the first week of October, again for a succession in December or January. The seeds are sown in shallow boxes $2\frac{1}{2}$ inches or 3 inches deep. Empty champagne cases do admirably if cut to make two boxes, one $2\frac{3}{4}$ inches deep, and the other $4\frac{1}{2}$ inches; the latter I find useful to grow them in later on. The size I use are about 20 inches long by $13\frac{1}{2}$ inches wide, which accommodate about 100 seeds at $1\frac{1}{4}$ inch to $1\frac{1}{2}$ inch apart all ways. The boxes must be thoroughly drained and have a few rough leaves laid over the drainage. I fill the boxes nearly to the edges with a mixture of equal proportions of rough leaf soil, not sifted, and rough turfy loam with sufficient sand to insure porosity, and the soil is pressed firmly and evenly; on the top about a quarter of an inch of the same

mixture passed through a fine sieve is scattered in which the seeds are distributed in small holes made with the finger at the requisite distances apart; the seeds are then covered with a layer of the fine soil.

A thorough watering through a fine-rosed water pot must then be afforded, and the boxes can be placed in any cold but frost-proof pit or frame, and may be stacked on each other if several are sown at the same time, with a slate or pane of glass on the top one. This will keep them uniformly moist. If the seeds are sown the first week in October (or earlier) the boxes should remain in the cold pit for a fortnight, being examined occasionally to see that they do not become dry. They should then be removed to a structure where a temperature of 55° to 60° can be maintained, and the majority of the seeds will have germinated in from a month to six weeks from the time of sowing; a sharp look-out must be kept for woodlice, which devour the seedlings unless they are trapped. The boxes should then be raised as near the glass as possible, and have sufficient water to keep the soil pleasantly moist and be lightly syringed on fine bright days; air must be given on all favourable occasions to keep them as sturdy as possible. Soft water should always be used for syringing, as water containing lime spoils the foliage.

The little plants should remain in the boxes in which the seeds were sown until about the middle of February. Then commence by preparing a suitable number of boxes $4\frac{1}{2}$ inches deep by thoroughly draining them and filling with a compost of equal parts of rough leaf soil and good fresh turfy loam; to make sure of there being no grubs or wireworms present I roast the soil on large tins. I then add some old mortar rubble and sand, thoroughly mixing and slightly moistening if necessary. The boxes are placed in the same temperature as the plants to become warm, and on the following day the plants (which by this time have from three to five leaves) are carefully lifted with a pointed stick and transplanted twenty-four in a box of the size previously mentioned; with one good watering to settle the soil, frequent applications will not afterwards be required. The syringe must be used daily, and the boxes still be kept in the heated pit.

In about eight or ten weeks from the time they were transplanted they will have almost covered the soil with leaves, and preparations should be made for placing them in the flowering pots. A similar compost as before may be used, and sufficient new or clean 5-inch and 6-inch pots should be drained, each having a handful of old mortar over the crocks. See that the mould in the boxes is moist throughout, as the plants will then lift with balls of soil attached to the roots; the larger may go into 6-inch and the remainder 5-inch pots. The soil should be pressed moderately firmly in the pots, working it round the sides with a thin rammer and leaving the top of the corm just above the surface of the soil. Return the plants to the same pit as before, where they should remain until established in the pots, and be watered and syringed as before. In two or three weeks they ought to be removed to an unheated pit or frame, and kept rather close for a time to inure them to cool frame treatment. This is usually done early in June, and for a week or two the pots may stand closely together, but by midsummer they should be plunged in ashes to the rim a good distance apart, and within 6 inches of the glass.

The plants will require watering carefully at this stage until, in fact, the pots become filled with roots, when abundant supplies are necessary, also syringing each morning, and again about three o'clock on bright warm days. Shading must also be carefully attended to, but should not be overdone, as they will be found to stand more sun than is usually allowed them. I generally put on the tiffany, or similar material, about 10.30 or 11 A.M., and remove it again about 3 P.M., or before if dull; much depends on the weather, as on some days no shade whatever is required. The plants must have ample ventilation by night as well as by day. I use small blocks about 2 inches thick for the front of frames, one under each side of the lights, and a single 6 or 8-inch block at the back; this tends to keep the plants sturdy, and during August and early part of September the lights may be withdrawn at night, as the plants seem to enjoy the dews which are then prevalent. Weak liquid manure should be given at each watering, as soon as the pots are full of roots.

Towards the end of September many plants will be coming into flower, and all will be full of buds, and ought to be removed to the greenhouse or conservatory, where they will flower all through the winter. I find it a good plan to arrange them in blocks of two or three dozen plants of separate colours—viz., whites, crimsons, rose, and other shades; this gives them a telling and distinct appearance. By the above system I find Cyclamens much easier to grow than Pelargoniums, and they are splendid for cut flowers. I omitted to mention that if green fly should put in an appearance in the early stages whilst in the heated pit I vapourise them with nicotine compound, and when in the cold frames, being somewhat difficult to vaporise, I have found syringing or spraying with quassia extract or XL-All liquid insecticide excellent.—J. JUSTICE, *The Nash, Kempsey, Worcester.*

[The specimens sent by Mr. Justice included both flowers and foliage, which were equal in colour, substance, and form to any we have seen.]

Mentmore: The Seat of the Earl of Rosebery.

IN the records of contemporary horticulture there are certain numbers of estates in various parts of the country which are recognised as conspicuous examples of general excellence. Their celebrity does not hinge on one particular feature, as their owners and managers do not seek for popularity with one section, preferring to shine in the broadest domain of the real world of horticulture. Neither do they take up the cultivation of Chrysanthemums, or Roses, or Apples, or Potatoes, and, concentrating the whole of the available forces on one of these,

can find no evidence of modernity in the magnificent trees that abound, and which in the splendid growth they have made speak volumes in praise of the fertility of the soil and the skilfulness of the attention that has been bestowed upon them. They have in attaining a rapid maturity added age and dignity to the estate of Mentmore until it has come to be recognised as a home of arboriculture and of horticulture in its broadest sense.

From the Railway.

Holding as it does amongst horticulturists such an enviable reputation, it seems scarcely necessary to state that the demesne lies to

produce specimens of unparalleled excellence as they might easily were they so minded. Instead of this all these products are grown, and more, with such striking success that every crop becomes so to speak a specialty, and the gardener a specialist in all departments of gardening. Such estates are becoming fewer and fewer in numbers as the result of circumstances that would be readily explainable in the proper place, which is not the pages of the *Journal of Horticulture*.

Hence it is that those now remaining as illustrative of the many existing, shall we say a generation ago, deserve more than ordinary notice, and as Mentmore must be included amongst them, it is now proposed to give it, by the aid of the camera and letterpress, attention commensurate with its importance. Mentmore could not, as all the world knows, be brought within the category of old estates, as it owes, in the main, its origin and growth to the past half century. That there existed a manor and grounds of Mentmore prior to the date given must be admitted, but we are now regarding it from a purely horticultural point of view, and as such it must be designated new. But one

the left of the town of Leighton Buzzard, and slightly over two miles from Cheddington station, on the London and North-Western Railway. It is probably a fact, however, that hundreds of persons interested in gardening, and thousands of the general public, are not aware that an admirable view of the range of fruit houses at the top of the vegetable garden can be had from the train as it passes Cheddington station on its northward journey. Many times has this garden been remarked upon by travellers who have speculated as to the ownership of the estate. The distance from London is about thirty-eight miles, and readers of these notes who have not yet enjoyed the peep may do so on the next occasion that they make a pilgrimage on the railway specified. From a purely horticultural aspect there is little to interest the traveller on either side of the line, so that it may at once be assumed that we have detrained at Cheddington Junction, and are rapidly advancing towards the entrance to Mentmore. We have, however, a considerable drive ere the splendid gardens, the diversified pleasure grounds, and the mansion are reached.

Amidst the Damsons.

Scarcely five minutes will have passed after leaving the station before there will appear on either hand evidence of one of the industries of the surrounding country—Damson growing. Of these fruits there are scores of acres in the neighbourhood, and as a Damson producer it must rank with the Pershore district of Worcestershire and one or two

FIG. 58.—MENTMORE: IN THE SUBTROPICAL GARDEN.

others. Writing of the industry in the Journal some half-dozen years ago, an authoritative writer said, "That they (Damsons) pay remarkably well scarcely needs telling, as it is very certain such shrewd business men as Lord Rosebery and his experienced gardener (Mr. Smith) would not go on establishing orchards of them for the benefit of the estate and those who rent the farms if Damsons were 'played out.' But for the Damson orchards it is very probable many of the farmers would have been bankrupt ere this. Thirty acres of trees cost very little to keep in good order, and they rarely fail to produce heavy crops. It must be borne in mind that the soil, a mixture of chalk and clay, suits the trees admirably, this promoting that exceptionally robust productive habit so essential to success. Quite young trees bear well, while the older ones seem, when the fruit is ripe, to be a mass of purple. In addition to the orchards formed and handed over or let to the tenants, Lord Rosebery has about a hundred acres of Damsons on his own hands, Mr. Smith having sole charge." The writer gives many other interesting details, and concludes with the following remarks, that are as pertinent now as at the moment when they were written, and which point a moral in packing that might well be taken to heart by many fruit growers. "The Mentmore Damsons always sell well, no matter how heavy may be the crops, owing to the reputation gained for honest packing. There is no forming a top layer with picked fruit while that underneath is much mixed, and it pays better to throw or give inferior fruit away than to mix it with better samples."

From the Station.

A few yards beyond the orchards, with an intervening single line of railway, and the drive to Mentmore Gardens is entered upon in real earnest. On the day of my visit the face of Nature was clothed in all the purity of a snowy mantle, and from the trees the hoar frost hung in festoons, and decked each minute twig in chaste winter finery. There were something over 20° of frost, and the keen air acted as an invigorating tonic after the enervating influences of London in winter. This approach is flanked by circular groups of trees and Conifers, each,

apparently, some 50 or 60 yards in diameter, and the same distance apart, and still farther from the road. In the spaces between the groups are specimen Wellingtonias, which have ample room to show their development. There is no cramping; on the contrary, a bold aspect has been insured by this system of planting. The trees show admirably on the grass, which is kept short, but is never cropped closely with a lawn mower. The ground here is nearly level, the soil being clay with an admixture of chalk, and of whose fertility the trees speak plainly. The drive continues thus for a considerable distance, and then rises to the village of Mentmore, with the mansion, flower gardens, and park on the one hand, and the vegetable and fruit gardens on the other. Of the village and its features something more will be said later; in the meantime, however, a little history will not be out of place, especially as it has considerable bearing on what has been said in the opening paragraphs.

History: The Mansion.

Mentmore, as above indicated, is a comparatively new place, the mansion having been commenced in 1851, and completed in a few years by the late Baron Meyer de Rothschild. It is interesting to observe that the designs for this splendid building were supplied by Sir Joseph Paxton, M.P., and his son-in-law, Mr. George Henry Stokes, architect. The style adopted, by desire of the Baron, for the exterior has been described as that which prevailed during the early part of the reign of King James I. The combination and arrangement have contributed to produce grouping of a picturesque character and outline, and the details and ornamentation are

understood to be the result of a careful study and examination of the works of John of Padua. The mansion is built entirely of Ancaster stone, of fine quality and colour; the cornices are highly enriched, and the frieze of each order is filled in with carved panels and heads. The arrangements and decorations of the interior are on a similar scale of grandeur, and altogether this is one of the most magnificent houses of the great that adorn our land—at once an embodiment of wealth and stability, and typical of the character of the "sea-girt isle." In the three photographic illustrations, numbered respectively 57, 59, and 61, are given different aspects of the mansion, and these will largely assist in conveying to the mind of the reader an idea of its ornate splendour.

History: The Gardens.

The gardens have been formed and the grounds planted by degrees, something being added and something done every year until in the aggregate the work accomplished is of great magnitude. At first the Baron would have 10 gardens, but Covent Garden should furnish him with the requisite flowers, fruits, and vegetables. Then he would grow a little fruit, and orchards were planted, which now extend to scores of acres. He did not like glass structures, but eventually one house might be built. A strip might be had for growing a few vegetables, and boarded fences for training trees. Now there are nearly 20 acres enclosed with walls, and one of the finest collections of fruit trees in the kingdom. This has Mentmore grown, and the pleasure grounds have increased in a similar manner, Mr. Smith, with a large staff, adding and improving every year, carrying out his own designs after approval by his employers, and completing whatever work he has in hand in the best manner. He evidently works on the principle, and a most excellent one it is, that is embodied in the aphorism, "First see your way, then go ahead." A headlong rush into alterations without due consideration frequently necessitates work having to be done again, while he who commences an undertaking without a clear perception of the ultimate result, practically labours in the dark. Neither of these mistakes, both of which are somewhat too common, is made at Mentmore.

The Main Drive.
